Re: Las Posas Valley Basin Groundwater Sustainability Plan (GSP)

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Fox Canyon Groundwater Management Agency's Las Posas Valley Basin (LPVB) Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We appreciate that the GSA incorporated a portion of our feedback (10 of 25 comments were addressed), however, we disagree with the components where our feedback was ignored or dismissed. This suggests a limited degree of engagement of environmental beneficial users and could result in a definition of sustainability that is biased towards a limited set of users in the basin. In our experience, the GSP did not "adequately respond(d) to comments that raise credible technical or policy issues with the Plan," (23 CCR §355.4(b)(10).

Regarding the GSP development process, TNC would like to commend the GSA for including an environmental representative, a TNC staff member, on the Technical Advisory Group (TAG). This inclusion enabled TNC to voice concerns on behalf of environmental beneficial users the GSP development process. The quality of portions of the plan benefitted from the ad hoc TAG subcommittee that was formed to evaluate GDEs in the subbasin. The impact of this group extends beyond this GSP because their efforts helped to develop a GDE guidance document that is now being used by dozens of GSAs across the state. In addition, a special TAG public workshop was convened to discuss GDEs and solicit input from the public. TNC, many other environmental non-governmental organizations (NGOs), and federal resource agency provided feedback on the draft GSP.

TNC recommendation: We recommend that DWR require the GSA to prioritize stakeholder engagement, resulting in stakeholder input being incorporated into the plan. Improvements can be achieved through enhancements to the stakeholder engagement plan, partnerships with NGOs and community members, more representative governance and funding decisions.

Interconnected Surface Waters – The GSP incorrectly excluded actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). Arroyo Simi–Las Posas is a complex series of gaining and losing reaches that are connected to the Shallow Alluvial Aquifer. The GSP spatially identifies ISWs and includes a brief overview of the gaining and losing reaches of the Arroyo Simi–Las Posas based on source water data, streamflow gages, and a field study of the gain and losing reaches with an estimated recharge rate from Arroyo Simi–Las Posas to Shallow Groundwater. This study was performed in September 2011, during an average water year and revealed that the arroyo is a complex series of gaining and losing reaches. In fact, the groundwater levels are sufficiently high so that groundwater connects back to the surface of the arroyo in the middle stretch of the arroyo. We strongly disagree with incorrect language throughout the GSP stating that the arroyo is a losing stream and that the surface water and groundwater are disconnected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystems – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 537 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

While we were pleased to see that GDEs were identified and mapped, the GSP did not consider GDEs as a beneficial user throughout the plan. We recommend that the GSP be revised to consider GDEs, as a beneficial user, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

The GSP characterizes the riparian ecosystem around the Arroyo Simi-Las Posas as a potential GDE due to perennial flows provided by non-native source waters. The riparian ecosystem around the Arroyo Simi-Las Posas should be considered a GDE. It should *not* be characterized as a *potential* GDE. There are sufficient data and studies (CMWD 2012, 2013) that demonstrate the connectivity of the GDE and the source water replenishing groundwater. It must be emphasized that the recognition of the non-native source waters does **not** negate this groundwater-surface water connectivity. GDEs are "ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" (23 CCR §351 (m)). By definition, the water source does not play a part in the *identification* of GDEs and thus the focus on "native flow" in identifying the GDE is incorrect. See Identification, Mapping and Description of GDEs Section in Attachment B. GDEs are a beneficial use of groundwater and the criteria are intended to prevent significant and undesirable impacts to beneficial uses of groundwater under current and future conditions. Given potential future conditions with decreased discharge from the Simi Valley and Moorpark wastewater facilities, the Arroyo Simi-Las Posas GDE should be considered in the sustainability goal and sustainability criteria should be defined for interconnected surface water [see Undesirable Results Section in Attachment B].

TNC recommendation: The GSP utilizes groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in our BMP guidance document (Attachment D) to identify and consider GDEs in the GSP. Specifically, please ensure that a Digital Elevation Model (DEM) is used when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and/or managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). The GSP lists (Table 2-7) riparian evapotranspiration (ET) rates that are not consistent with the rates in the Technical Memorandum: Summary of Additional Refinements to the Groundwater Model of East and South Las Posas Sub-Basins (Intera, 2018), this discrepancy is not clarified in the text, and estimated riparian ET is attributed to arundo (an invasive species subject to management actions). The GSP only focused

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

on a subset of water use sectors, such as urban and agricultural users of groundwater, and water sources outside the FCGMA's area that are "out of their control". Water sources need to be adequately differentiated and understood prior to disregarding ISWs and GDEs. This is problematic because key environmental uses of groundwater are not being accounted for as water supply decisions are made using this budget nor will they likely be considered in project and management actions.

<u>TNC recommendation:</u> As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

<u>TNC recommendation</u>: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

The Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater.

<u>TNC recommendation:</u> TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Groundwater Sustainability Plan for the Las Posas Valley Basin

The complete Final GSP for the Las Posas Basin, adopted December 13, 2019 as Resolution 19-05, was reviewed by TNC. TNC submitted comments on the Public Draft GSP on September 17, 2019. However, specific responses to comments on the Public Draft were not publicly available so we compared the Public Draft GSP to the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the Fox Canyon Groundwater Management Agency during the public comment period, and states whether or not they were addressed in the Final GSP [as green text within brackets]. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 1.8.2 – Summary of Beneficial Uses and Users (p. 1-32) and Table 1-9 (p. 1-46)]

- *[Minor changes to GSP text do not adequately address the comment.]* We find the characterization of the Arroyo Simi–Las Posas GDE as a losing stream to mischaracterize the groundwater-surface water interconnection and thus it inappropriately concludes that the riparian plants are "using percolating surface water rather than groundwater". The Arroyo Simi–Las Posas should be characterized as a complex system of losing-gaining-losing reaches across the LPVB; groundwater is shallow and the riparian ecosystem likely uses a combination of unsaturated soil pore water and groundwater to supply its water needs. The GSA has included representation of environmental users on their Technical Advisory Group (TAG), in a special meeting on GDEs and in GSP email and meeting notifications. We also recommend that the GSP specifically list the natural resource agencies, NOAA's National Marine Fisheries Service (NMFS), United States Fish and Wildlife Service (USFWS), and California Department of Fish and Wildlife (CDFW), as stakeholders since they are important parties representing the public trust. In addition, both the CDFW and the USFWS agencies have attended the special TAG GDE meeting.
- *[Our comment has been adequately addressed through GSP text changes. Thank you for making this change that promotes better delineation of native habitat and its environmental value.]* In Table 1-9, please revise the Land Use Category from "Vacant" to "Open Space". As noted in Section 1.3.2.3 - Historical, Current, and Projected Land Use and Section 1.6.1 – General Plans, this is a substantial acreage that is valued highly in Ventura County as open space, with ordinances such as the 1998 Save Open Space and Agricultural Resources ordinance. We need to do a better job of delineating open space and native habitat from the "vacant" category, as this

devalues the environment and its water need. The Executive Summary (p. ES-3) correctly describes the land use as open space.

Checklist Items 6 and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 2.2 Hydrogeologic Conceptual Model]

- *[Minor changes to GSP text do not adequately address the comment.]* Section 2.2 should be revised to incorporate the latest knowledge provided by the Epworth Gravels Management Area (ELPMA) groundwater model (Intera, 2018). The characterization provided both in the analysis (e.g., Section 5.0 Groundwater Occurrence and Movement) and by the numerical model provide a much fuller understanding of the hydrogeological conceptual model.
- *[Minor changes to GSP text do not adequately address the comment.]* The Hydrogeologic Conceptual Model should describe the shallow groundwater that is interconnected with surface waters and GDEs. There is a brief mention of a "shallow aquifer system" in the West Las Posas Management Area (WLPMA) in Section 2.2 - Hydrogeologic Conceptual Model. There is no discussion of this in Section 2.2.1 - Geology. The description of the Recent Alluvium mentions only the "aquifer beneath the floodplain of Arroyo Simi–Las Posas." Hydrogeologic Conceptual Model The description of the Shallow Alluvial Aquifer in Section 2.2.4 – Principal Aquifers and Aquitards, which was specifically stated as being in the ELPMA, there is a statement that doesn't belong: "The alluvium is also present in the WLPMA in Beardsley Wash and Ferro Ditch (Figure 2-2)." Presumably, this is an attempt to discuss the "shallow aquifer system" in the WLPMA. Figure 2-4 shows the "Shallow Alluvial Aquifer" extending from the Wright Road fault to Bradley Road. In contrast, the UWCD model only includes aquifers of the Upper Aquifer System (UAS) extending to about ½ mile east of the Wright Road fault (UWCD, 2018). As summarized in Table 2-10a, the pumping data (average of 1,397 AF/yr) for the shallow aquifer system and the water budget numbers from the UWCD numerical model indicate this is a water producing aquifer. These different statements lead to a significant amount of confusion by the reader. This shallow aquifer system should be much better characterized in Section 2.2.4.

  In particular, our concern for clarity is in regards the potential for this shallow aquifer to support any potential GDEs, such as the riparian ecosystem identified in the Beardsley Wash. Earlier discussions during TAG meetings had indicated that there was **not** a shallow aquifer unit in WLPMA. Thus, the riparian habitat along the Beardsley Wash were assumed to be supported during dry summer periods by agricultural runoff, and/or residential development outdoor water use and excluded from further consideration (see Appendix I). This needs to be reconsidered.

- *[Our comment has been adequately addressed through GSP text changes. Thank you for clarifying the currently available data and knowledge.]* Section 2.2.4 (p. 2-10): The statement: "Currently, there are few wells that produce water from the Shallow Alluvial Aquifer, which is likely a result of the marginal-quality water and low well yields compared to the FCA [Fox Canyon Aquifer]" is misleading. The Calleguas

Municipal Water District's (CMWD) numerical model report (Figure 7-11, Intera, 2018), shows at least 30 production wells in the Shallow Alluvial Aquifer. Figure 1-7 shows a significantly different set of wells. Section 2.4 - Water Budget, indicates an average pumping rate in the Shallow Alluvial Aquifer of 383 AF/yr, with a range from 203 to 972 AF/yr over the historical period.

[Section 2.3.1.2.1 Shallow Alluvial Aquifer: Vertical Gradients (p.2-20)]

- *[No changes to GSP text made.]* This section only refers to the one nested well pair in the Shallow Alluvial Aquifer. That one data point indicates a small upward gradient and thus presents a very confusing picture of the flow from the Shallow Alluvial Aquifer to the Upper San Pedro since it is very well established that there is a downward vertical gradient through the Shallow Alluvial Aquifer through the San Pedro and also down to the Fox Canyon.

<u>Checklist Items 8, 9 and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16); and Identification of ISWs is a required element of Current and Historical Groundwater Conditions (23 CCR §354.16)</u>

[Executive Summary; Sections 1.3.2.1, 2.3.6, 2.3.7, 2.4.1.1, 2.4.2.5, and Appendix K]

- *[Minor changes to GSP text do not adequately address the comment.]* Arroyo Simi–Las Posas is a complex series of losing, gaining and losing reaches that are connected to the Shallow Alluvial Aquifer. ISWs have been spatially identified, including a brief overview of the gaining/losing reaches of the Arroyo Simi–Las Posas based on source water data, streamflow gages, and a field study of the gain/losing reaches with an estimated recharge rate from Arroyo Simi–Las Posas to Shallow Groundwater. This study was performed in September 2011, during an average water year and reveals that the arroyo is a complex series of losing, gaining and losing reaches. In fact, the groundwater levels are sufficiently high and water surfaces back to the arroyo in the middle stretch of the arroyo. Figure 2-16 maps out the losing and gaining reaches and presents a clear understanding of the interconnected system in ELPMA. We strongly disagree with misleading language throughout the GSP stating that the arroyo is a losing stream and that the surface water and groundwater are disconnected. These include:
    - Executive Summary - (ES.2) Summary of Basin Setting and Conditions (p. ES-6) "Increased surface water flow and infiltration along Arroyo Simi–Las Posas also resulted in the establishment of riparian vegetation, along the banks of the arroyo. This riparian vegetation, which is dominated by non-native Arundo (*Arundo donax*), has been identified as a potential groundwater-dependent ecosystem. Within the boundaries of the ELPMA, Arroyo Simi–Las Posas is generally a losing stream, meaning that the groundwater table is below the stream bed, and water from Arroyo Simi–Las Posas percolates into the underlying sediments to recharge the groundwater. This leads to the conclusion that the riparian habitat along Arroyo Simi–Las Posas may rely on soil moisture from percolating surface water, rather than groundwater. As surface flows and recharge decrease in Arroyo Simi–Las

Posas, groundwater elevations and soil moisture content in the vicinity of the potential groundwater-dependent ecosystem are anticipated to decline. These declines may impact the health of the riparian vegetation."

This language is misleading as it portrays a disconnected groundwater-surface water ecosystem. The Arroyo Simi–Las Posas is a mix of gaining and losing reaches and *is* connected to the Shallow Alluvial Aquifer. Only at the LPVB boundary, where the Arroyo Las Posas has gone dry since 2012, is there a disconnection between the surface water and groundwater. Ecosystems often rely both on groundwater and surface water to meet their water needs (see Best Management Practice #3 in Attachment D of this letter). A strictly binary approach, designating all GDEs as either 100 percent reliant on groundwater or 100 percent reliant on surface water supplies is therefore inconsistent with the available science. The above "conclusion" is conjecture and the statement should be revised.

- Executive Summary - (ES.3) Overview Of Sustainability Criteria (p. ES-9) "Depletion of interconnected surface water is not occurring within the LPVB, where Arroyo Simi–Las Posas is a losing stream, with groundwater elevations that have been below the bottom of the stream channel for decades." This is not an accurate statement, as Arroyo Simi–Las Posas is a mix of losing and gaining reaches and the groundwater elevations have been stable and high enough to intersect the stream channel for the past few decades. We do agree that depletions of ISWs are not occurring for the majority of the GDE, except along the LPVB boundary with Pleasant Valley, as noted above.

Checklist Items 11 to 20 - Identification, Mapping and Description of GDEs (23 CCR §354.16)

[Section 2.3.7 Groundwater-Dependent Ecosystems and the Executive Summary]

- *[Minor changes to GSP text do not adequately address the comment.]* GDEs have been identified and mapped during the GSP development process using an earlier version of the statewide database of GDE indicators (iGDE v0.3.1; TNC, 2017) and TNC's GDE Guidance document (Rohde et al., 2018). This evaluation is described in Appendix I, with a brief summary in Section 2.3.7. In addition to the mapping of basin GDEs, it also includes both an assessment of the hydrologic and ecological conditions of the GDEs and potential GDEs.

  The Arroyo Simi–Las Posas *should* be considered a GDE. It should *not* be characterized as a *potential* GDE. Non-native flows from the Simi Valley and Moorpark waste water treatment plants and the Simi Valley groundwater dewatering wells have both provided perennial flows in the Arroyo Simi-Las Posas and filled the Shallow Alluvial Aquifer such that under current conditions, the Arroyo Simi-Las Posas and Shallow Alluvial Aquifer is an interconnected system. There are sufficient data and studies (CMWD 2012, 2013) that demonstrate the connectivity of GDE and the surface water itself. It must be emphasized that the recognition of the non-native source waters does **not** negate this groundwater-surface water connectivity. GDEs are "ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" (23 CCR §351 (m)). By definition, the water source (native or non-native) does not play a part in the *identification* of GDEs. The focus on "native flow" as defining a GDE is a fundamental flaw. The source of water entering an aquifer has never been a factor in defining groundwater. In fact, about 93% of the inflows into the ELPMA are from non-native sources (see Table 2-7) yet the GSP considers all of it groundwater.

There are many misleading statements that attempt to discount the groundwater-surface water connection and the Arroyo Simi–Las Posas GDE by overemphasizing the water source. We request that such statements be revised or removed. These include:

- Executive Summary – see above listed language
- *[Text was removed from the final GSP]* (Section 2.3.7, p. 2-36) "However, the riparian vegetation in the Arroyo Simi–Las Posas composing these potential GDEs was established and is maintained by discharges from wastewater plants and Simi Valley dewatering discharges to Arroyo Simi."
- *[Text was removed from the final GSP]* (Section 2.3.7, pp .2-36 to 2-37) "The gaining reach is caused by surface water that is resurfacing rather than by discharge of native groundwater (CMWD 2012, 2013)."
- *[Text was removed from the final GSP]* (Section 2.3.7, p. 2-38) "Until a connection between groundwater elevations under native flow conditions and the potential GDE is established, the Arroyo Simi–Las Posas potential GDE cannot be conclusively determined to be a GDE."

Again, the source of the groundwater, native or otherwise, does not alter the fact that it is groundwater and therefore should be considered as such when evaluating whether it supports a potential GDE.

- *[Minor changes to GSP text do not adequately address the comment.]* The confusing information about the shallow aquifer in WLPMA, which was not presented in the 2017 Preliminary Draft GSP, needs to be assessed as to whether there is a hydrologic connection to any potential GDEs, such as the riparian ecosystem identified in the Beardsley Wash. Earlier discussions during TAG meetings had indicated that there was not a shallow aquifer unit in WLPMA. Thus, the riparian habitat along the Beardsley Wash were assumed to be supported during dry summer periods by agricultural runoff, and/or residential development outdoor water use and excluded from further consideration (see Appendix I of the GSP). This needs to be reconsidered and described in Section 2.3.7.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 2.4 Water Budget]

- *[Minor changes to GSP text do not adequately address the comment.]* The water budget includes the Shallow Alluvial Aquifer in the ELPMA and the shallow aquifer in the WLPMA. In the ELPMA, the Arroyo Simi-Las Posas is a net recharge to the Shallow Alluvial Aquifer and the Arroyo Simi-Las Posas riparian vegetation evapotranspiration (ET) is a discharge from the Shallow Alluvial Aquifer. The riparian

ET is estimated as Arundo, and average ET is estimated as 1,062 AF/ac in Table 2-7. Section 2.4.2.2, Riparian Evapotranspiration Losses incorrectly describes the use of the consumptive water use of 24 AF/ac; The second paragraph correctly describes the calculation method of the ETo and crop coefficient. However, table 2-7 lists riparian ET rates that are not consistent with the rates in the Technical Memorandum: Summary of Additional Refinements to the Groundwater Model of East and South Las Posas Sub-Basins (Intera, 2018).

Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)

[Section 3.1 Introduction to Sustainable Management Criteria (p. 3-1 to 3-2)]

- *[No changes to GSP text made.]* The FCGMA Board of Directors adopted planning goals in 2015 that "Promote water levels that mitigate or minimize undesirable results (including pumping trough depressions, **surface water connectivity** [emphasis added], and chronic lowering of water levels)."
- The GDEs should be considered in the sustainability goal. GDEs are a beneficial use of groundwater and the criteria are intended to prevent significant and undesirable impacts to beneficial uses of groundwater under current and future conditions.

Checklist Items 30 to 46 - Undesirable Results (23 CCR §354.26)

[Section 3.3.6 Depletions of Interconnected Surface Water (pp. 3-14 to 3-15)]

- *[The undesirable result associated with depletion of ISWs in the LPVB is unequivocally stated to be the loss of GDE habitat. We applaud that recognition.]* We do not agree with the misleading language that continues to be used to dismiss the groundwater-surface water connection. Please see comments above with respect to Interconnected Surface Waters and Identification, Mapping and Description of GDEs. This nonsensical concept of resurfacing surface water not being groundwater is used to conclude that there will not be significant and unreasonable effects on beneficial uses of surface water such as GDEs.
- *[Our comment has been adequately addressed through GSP text changes. Thank you for clarifying current groundwater conditions.]* We do agree that *current* groundwater conditions in the LPVB do not impact the volume of flow in Arroyo Simi–Las Posas and groundwater production from the ELPMA will not result in depletion of ISWs with significant and unreasonable adverse effects on beneficial uses of surface water.
- *[Our comment has been adequately addressed through GSP text changes. Thank you for clarifying potential future groundwater conditions.]* However, in the future, an anticipated cause of groundwater conditions that would lead to depletions of ISWs and impacts to the Arroyo Simi-Las Posas GDE is decreased discharge from the Simi Valley and Moorpark wastewater discharges and Simi Valley dewatering wells. These discharges are a very important source of inflow to the ELPMA providing nearly 40% of the total annual recharge, and would also lead to decreased surface water flows, disconnection of the surface water and groundwater, and lowering of chronic lowering of groundwater levels in the Shallow Alluvial Aquifer and Fox Canyon

Aquifer, and interbasin interflow from the Las Posas Valley Basin to the Pleasant Valley Basin.

- *[Our comment has been adequately addressed through GSP text changes.]* Such a change, however, is unrelated to groundwater production from the Shallow Alluvial Aquifer and is outside of the jurisdictional powers of the FCGMA to prevent. However, given the SGMA goal of management of groundwater that will promote water levels that mitigate or minimize any potential future undesirable results of depletions of ISWs and the associated Arroyo Simi–Las Posas potential GDE, TNC proposes inclusion of this aspirational goal (Section 354.30(g), Measurable Objectives) with recognition of the dependence on the continuation of these external water sources.
- *[Our comment has been adequately addressed through GSP text changes.]* Recognition that external constraints (i.e., potential future loss of out-of-basin source waters) can result impacts to ISWs and GDEs was discussed with the California Department of Water Resources (DWR) and State Water Resources Control Board (SWRCB) (June 8, 2017 meeting). In particular, DWR was noted that SGMA §354.30(g) states: "An Agency may establish measurable objectives that exceed the reasonable margin of operational flexibility for the purpose of improving overall conditions in the basin, but failure to achieve those objectives shall not be grounds for a finding of inadequacy of the Plan." It was recognized that striving for an "aspirational goal" would be appropriate in this circumstance. We recommend inclusion of the "aspirational goal" when setting sustainability criteria for ISWs and the associated Arroyo Simi-Las Posas GDE.
- *[Our comment has been adequately addressed through GSP text changes.]* Therefore, the sustainability goal would recognize that under circumstances where external constraints result in impacts to the GDE, the FCGMA would not be obligated to address those impacts, if it is at the expense of other beneficial users (e.g., cutting back groundwater extractions by agricultural users). The GSA would only be obligated to address impacts to the GDE caused by changing groundwater conditions resulting from pumping or groundwater management under the jurisdiction of the GSA that cause undesirable results.
- *[No changes to GSP text made.]* In WLPMA, there needs to be a revised evaluation as to any hydrologic connection between the shallow aquifer system and any potential GDEs identified in the NC Dataset.

[Section 3.3.7 Defining Undesirable Results (p. 3-16)]

- *[No changes to GSP text made.]* For ELPMA, addressing chronic lowering of groundwater levels and depletion of groundwater storage is assumed to be protective for ISWs. And, the ELPMA will be determined to be experiencing undesirable results if, in any single monitoring event, groundwater levels in 5 of the 15 key wells are below their respective minimum thresholds. Given that the future depletions of ISWs (and loss of the Arroyo Simi-Las Posas GDE) is only related to lowering of groundwater levels in the Shallow Alluvial Aquifer, this definition does not make sense. The two key wells in the Shallow Alluvial Aquifer should be assessed separately to determine whether there could be future undesirable results.

Checklist Items 27 to 29 – Minimum Thresholds (23 CCR §354.28)

[Section 3.4 Minimum Thresholds (p. 3-17)]

- *[No changes to GSP text made.]* The avoidance of undesirable results should include the aspirational goal of maintain groundwater levels in the ELPMA Shallow Alluvial Aquifer to prevent future depletions of ISWs and loss of the Arroyo Simi-Las Posas GDE.

[Section 3.4.2.6 ELPMA Minimum Thresholds – Depletions of Interconnected Surface Water (pp. 3-24 to 3-25)]

- *[No changes to GSP text made.]* The GSP defines the minimum thresholds to address chronic lowering of groundwater levels and depletion of groundwater storage are to be protective of the Arroyo Simi-Las Posas GDE. Two wells to monitor representative groundwater conditions were selected in the Shallow Alluvial Aquifer are 02N20W09Q08 and 02N20W12MMW1. The proposed minimum thresholds are 170 and 300 feet MSL for 02N20W09Q08 and 02N20W12MMW1, respectively. Both of these are significantly below the historical lows of 271 and 358 feet MSL and the current condition (represented by Fall 2015) of 271 and 369 feet MSL for 02N20W09Q08 and 02N20W12MMW1, respectively. We disagree and find these proposed minimum thresholds to be entirely inappropriate.

  Based on literature studies, groundwater depths within the range considered necessary for juvenile establishment of willows and cottonwoods, typical focal phreatophytic species for riparian ecosystems, are less than 10 feet and for mature vegetation growth are less than 20 feet (Stillwater Sciences, 2016). Site-specific knowledge of groundwater use by the riparian vegetation is not known at this time. Although the literature studies suggest 20 feet bgs is a reasonable minimum threshold value for the GDE, it is uncertain what is the actual site conditions in the Arroyo Simi – Las Posas GDE. The recommended key well (02N20W12MMW1), which is located outside of the GDE, has average depth to groundwater of 21 feet bgs at the well, with a range of 18 to 27 feet bgs. This well has a long-term representative time period (1996-present). The proposed minimum threshold of 170 feet MSL would represent a depth to groundwater that is 200 feet lower than the average water level; this would not be supportive of any riparian vegetation. We recommend a minimum threshold protective of the GDE at the historical groundwater elevation of 358.2 feet MSL.

  On the western losing reach of the GDE where key well 02N20W09Q08 is located, there has been a significant decrease in the vegetative health of the GDE since 2013. Water levels in key well 02N20W09Q08 average 38 feet bgs, with a range of 35 to 40 feet bgs (time period 2014 to present). Given that this well has only been monitoring groundwater levels since 2014, it is unclear what a realistic minimum threshold should be. Also, as the well is not actually within the GDE and ground surface elevations in this area are quite variable, accurately determining depths to groundwater within the GDE is the necessary first step before recommending realistically protective minimum thresholds. This should be done by the 5-year plan update.

In addition, there is an observed decline in ecosystem health in the western losing reach where key well 02N20W09Q08 is located that is visible in the remote sensing vegetation metrics, NDVI and NDMI (Figure 14, Appendix I). However, as shown in Figure 10 (Appendix I), there is a large range in the depth to groundwater in this losing reach. It is recommended that field-based work be conducted to accurately determine depths to groundwater within the GDE and thus support a site-specific minimum threshold for the GDE.

Following the precautionary principle, it is recommended that the minimum threshold for key well 02N20W12MMW1 be set at its minimum historical level (358.2 feet MSL). The recommendation recognizes there is uncertainty regarding these analyses herein regarding equivalent GDE depths and correlations with declining ecosystem health that can be addressed with additional field-based assessment and then revised in the next 5-year plan update.

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Section 3.5.2.6 Measurable Objectives – Depletions of Interconnected Surface Water (pp. 3-33 to 3-34)]

[Our comment has been adequately addressed through GSP text changes. Thank you for making this change that promotes the sustainability goal.] Current groundwater levels, as raised and sustained by wastewater plant and dewatering discharges, have been relatively constant since the 1980s and have provided for establishment and maintenance of the GDE. Under the current assumption that baseline conditions are representative of GDE conditions and thus currently represent sustainable conditions, our recommendation is therefore to set the measurable objective at the baseline average groundwater elevation. For the key wells 02N20W12MMW1 and 02N20W09Q08, it is recommended that the measurable objectives be set to 370 and 272 ft MSL, respectively. It is recognized that maintaining such levels is depended upon continued wastewater plant and dewatering discharges, though not regulated by the GSA. However, proposed projects in the GSP can ensure these sustainability criteria are met for the GDE beneficial use and continued recharge of Shallow Aquifer and Fox Canyon Aquifer.

No interim milestones are necessary given that current conditions are meeting the measurable objectives.

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

[Section 4.2.2 Surface Conditions Monitoring (p. 4-4)]

- *[No changes to GSP text made.]* The statement "Additionally, evapotranspiration from riparian vegetation lining Arroyo Simi–Las Posas impacts surface conditions by using surface water in the Arroyo" attributes the evapotranspiration (ET) from riparian vegetation as solely being from surface water. This assumption that all ET is from surface water is not verified. The CMWD numerical model specifically attributes the ET from groundwater. In reality, it is likely a combination of surface water, soil pore water, and groundwater. This is an area for further study as there are the ET of the non-native Arundo in the riparian ecosystem is potential water savings that is evaluated in Project No. 2 (see Section 5.3).

[Section 4.3.6 Depletions of Interconnected Surface Water (p. 4-10)]

- *[No changes to GSP text made.]* We recommend including remote sensing vegetative indices as a low cost approach to monitor baseline conditions of GDEs. TNC's free online tool, GDE Pulse (included as Attachment E), allows GSAs a way to assess changes in GDE health using remote sensing data sets; specifically, the Normalized Difference Vegetation Index (NDVI), which is a satellite-derived index that represents the greenness of vegetation and Normalized Difference Moisture Index (NDMI), which is a satellite-derived index that represents water content in vegetation.

[Section 4.6.5 Shallow Groundwater Monitoring near Surface Water Bodies and GDEs (p. 4-15)]

- *[No changes to GSP text made.]* We recommend continued monitoring of the existing set of shallow aquifer monitoring wells in the vicinity of the GDE to continue a record of groundwater conditions and to assess whether changes occur in the future (Figures 6-9, Appendix I): 02N19W09E01S, 02N19W0K01S, 02N19W08H02S, 02N19W07G01S, 02N19W07K04S, 02N20W12MMW1 (key well), 02N20W12MMW2, 02N20W12MMW3, 02N20W09Q08S (key well), 02N20W17J06S, 02N20W10K02S. Wells 02N19W0K01S, 02N20W12MMW1 (key well), 02N20W12MMW2, and 02N20W12MMW3 were not identified as monitored wells in Tables 4-3 to 4-5. Also, 02N19W08H02S was incorrectly listed in Table 4-3 as monitoring the Lower Aquifer System (LAS). These should be included. In particular, 02N20W12MMW1 is a specified key well.

  One limitation of this initial evaluation is that the estimation of groundwater levels in the GDE are approximated based on wells outside the GDE, using single point land surface GDE reference points. As a result, this analysis is a simplification of the groundwater depth representation for the Arroyo Simi - Las Posas GDE. In reality, the ground surface elevation varies as the GDE traverses upslope from the stream channel to the floodplain terraces and also longitudinally up or downstream. Refinement of the depth to groundwater mapping in the GDE would more clearly determine the impacts of decreasing groundwater levels on the riparian habitat. In particular, monitoring of groundwater levels in the GDE will characterize the degree to which the vegetation is reliant on groundwater. Mapping of the ground surface elevation in the GDE near the monitoring wells is a necessary task.

Checklist Items 50 and 51 - Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Sections 5.3 and 5.4 Projects No. 2 & 3 (pp. 5-4 to 5-10)]

- *[Our comment has been adequately addressed through GSP text changes. Thank you for recognizing the importance and values of EBUs.]* Because treated water inflows are critical to maintaining extractions rates for agriculture and other beneficial users including the Arroyo Simi-Las Posas GDE the FCGMA approved two projects to be evaluated in the GSP (Project No 2. - Arroyo Simi-Las Posas Arundo Removal, and Project No. 3 - Arroyo Simi-Las Posas Water Acquisition). These projects are focused on maintaining the inflows into the basin.

  According to Section 354.44 of the SGMA regulations, projects are to achieve the sustainability goals for the basin. It goes on to say projects must include a "description of the measurable objective this is expected to benefit from the project". Therefore, the ELPMA GSP must include a goal(s) and measurable objective(s) tied to the purpose of Projects 2 & 3. Initially this created a quandary for the GMA because it is important to maintain the inflows from the treated water discharges, but it is not within the GMA's authority to ensure they continue. The SGMA addresses this by allowing aspirational goal where the agency creates an objective that may exceed its operational flexibility but failure to achieve the objective is not grounds for a finding of inadequacy (see Sec. 354.30(g).

  It is extremely important to include the EBUs in the establishment of the SMC. The proposed ELPMA projects are multi-benefit projects, and grant funding for such projects are predicated on the establishment of that position. Because both projects have co-benefits to both groundwater supply and the restoration of native habitat, the projects have access to multiple sources of funding. Without such clarity in the GSP, there is no justification for conservation funding. TNC is partnering with another NGOs that have already started the IRWM grant process in anticipation of the arundo removal project. We also want to jointly work to find funds for purchasing the Simi outfall water.

Attachment C

Freshwater Species Located in the Las Posas Valley Basin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Las Posas Valley Basin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[2]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the CDFW's BIOS[3] as well as on TNC's science website[4].

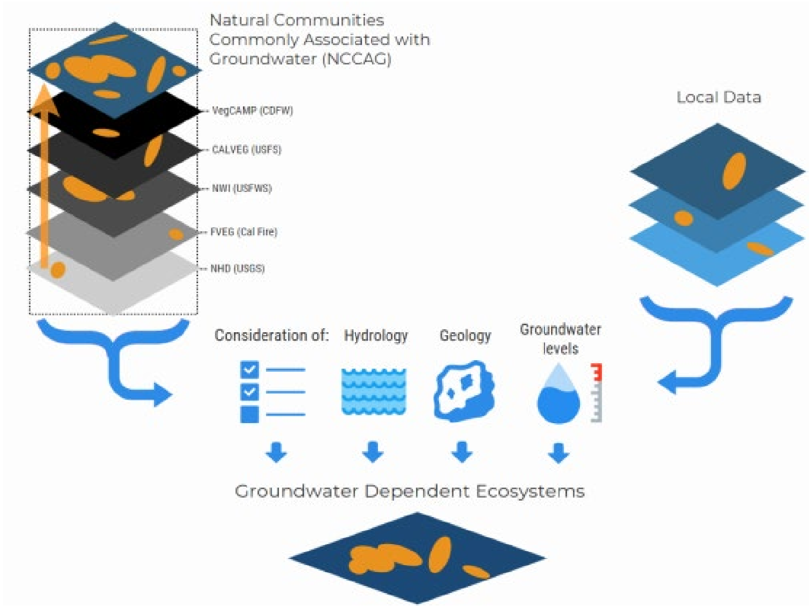
IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[5] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[6]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.

[5] *NC Dataset Online Viewer:* *https://gis.water.ca.gov/app/NCDatasetViewer/*

[6] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf



The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[7]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[8] on the Groundwater Resource Hub[9], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may

---

[9] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

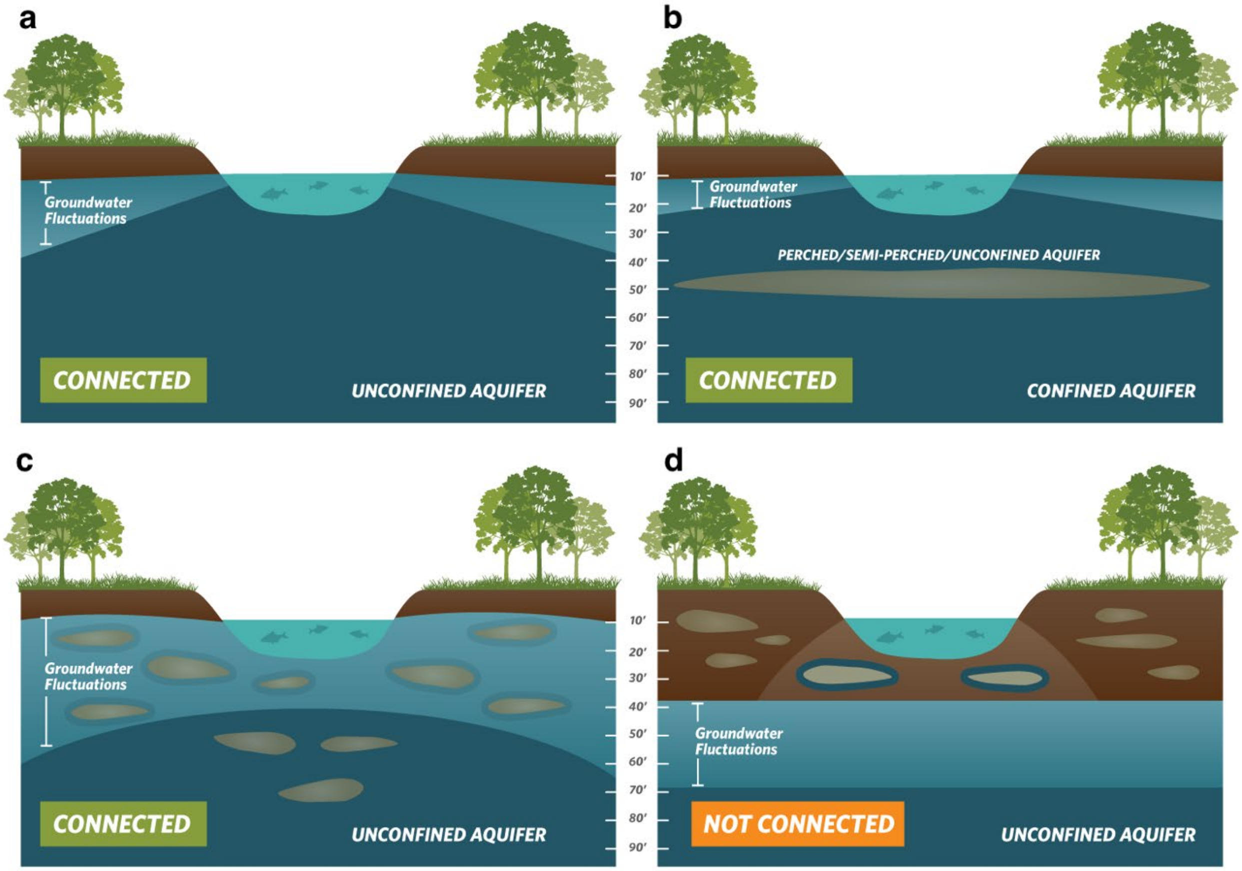

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[10] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[11] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[12] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[13]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

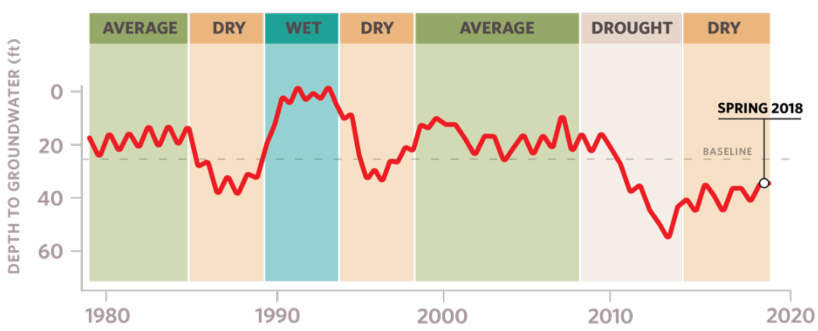

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[11] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[12] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[13] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[14], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

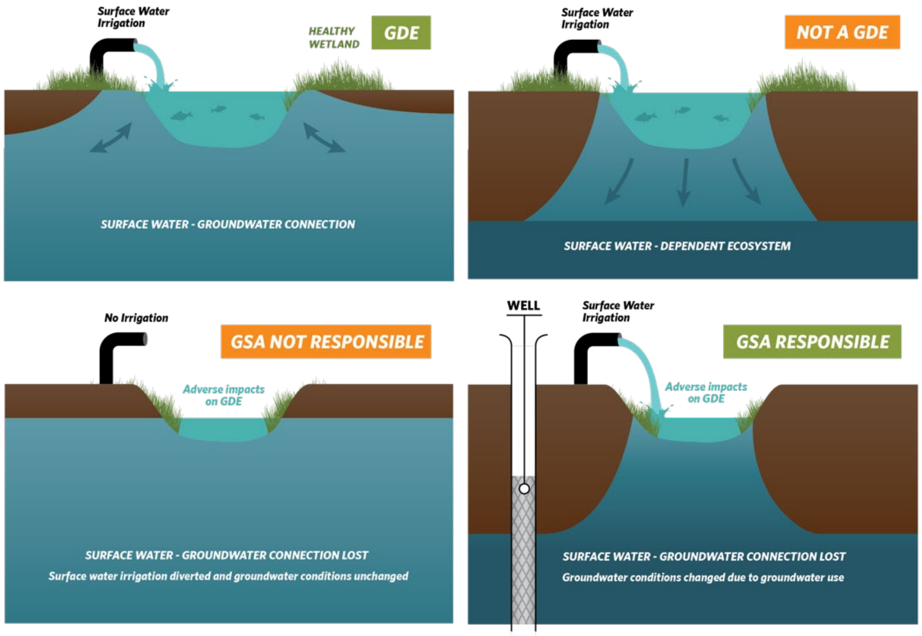

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[14] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

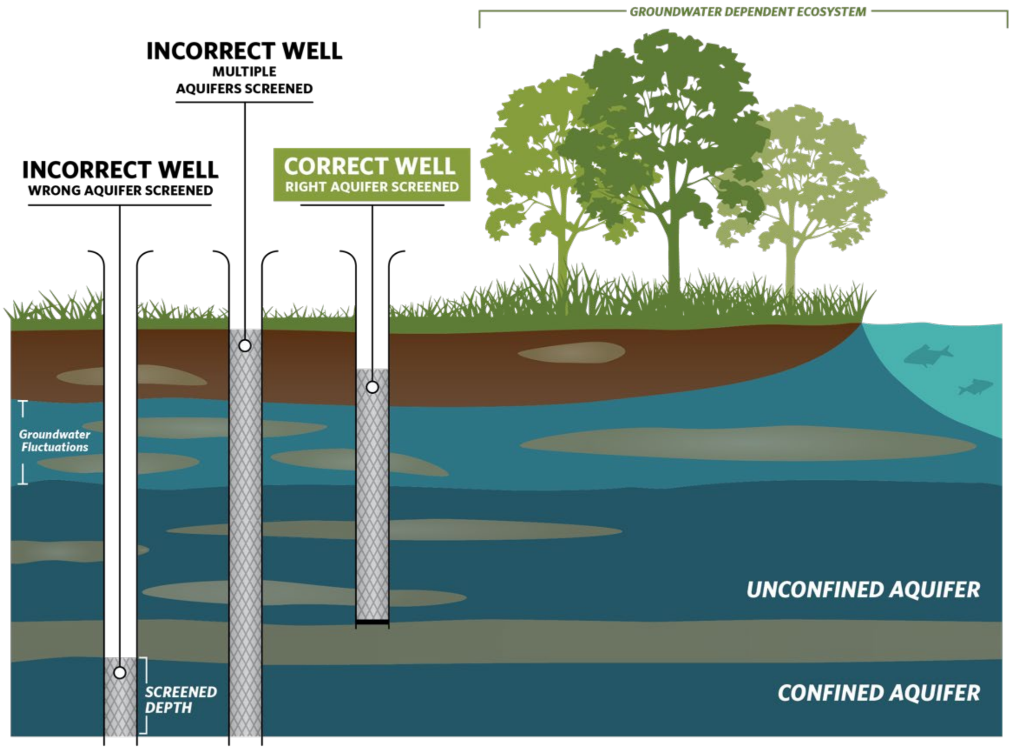

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[15] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

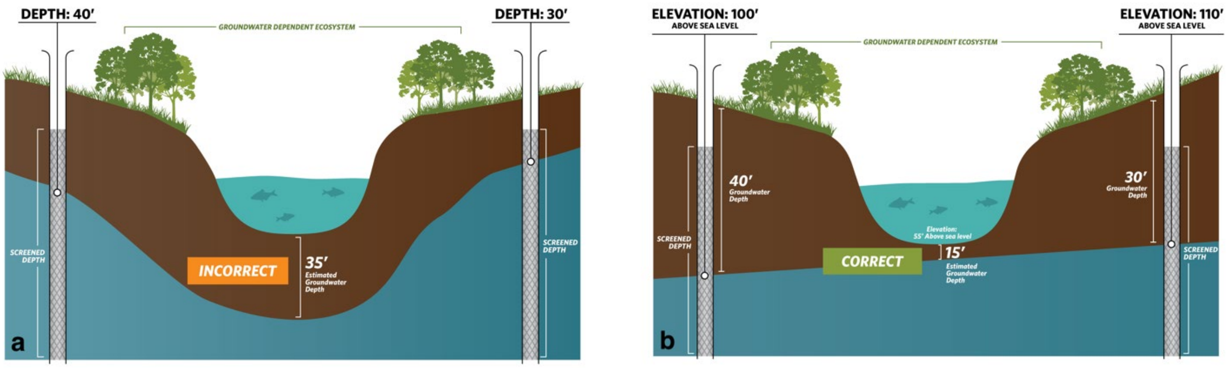

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

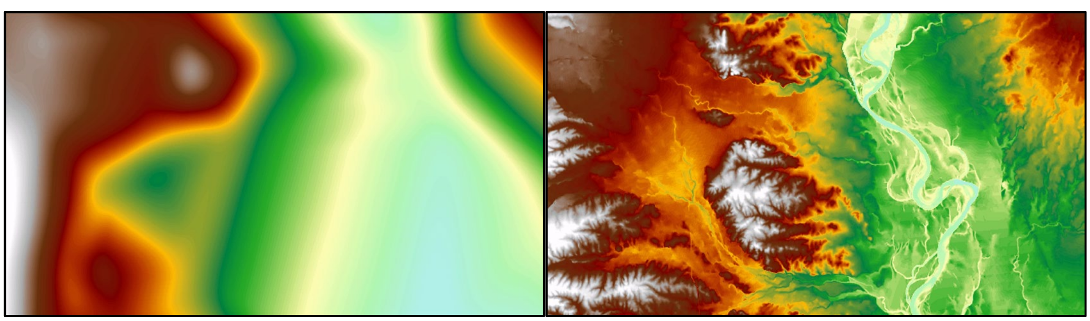

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[15] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

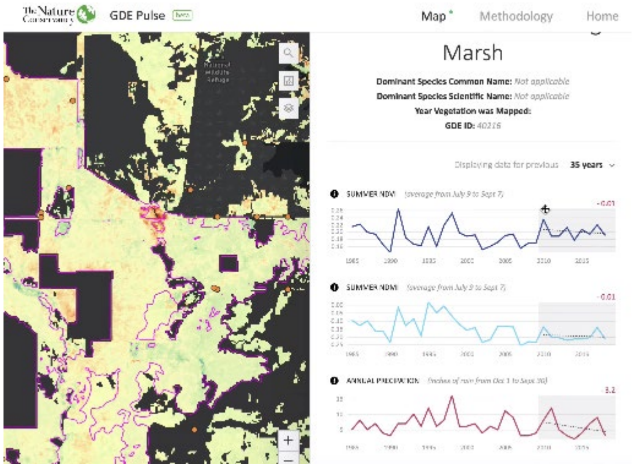
Attachment E

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

Protecting nature. Preserving life.®

Visit https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[16]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[17]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[18]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[19]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[20] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Oxnard Subbasin Groundwater Sustainability Plan (GSP)

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Fox Canyon Groundwater Management Agency's (FCGMA) Oxnard Subbasin Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be sufficient in addressing environmental beneficial uses and users.

We would like to compliment the GSA for their treatment of environmental beneficial users in the GSP. We believe the GSA sufficiently addressed environmental beneficial users in this first GSP submission. In the spirit of continual improvement embedded in SGMA, we would like to offer the following input as areas for improvement in the next version of the GSP.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data.

<u>Our Key Considerations</u>

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We would like to commend the GSA for incorporating our feedback, indicating strong engagement of environmental beneficial users. In addition, we would like to commend the GSA for including an environmental representative, a TNC staff member, on the Technical Advisory Group (TAG) throughout the GSP development. This inclusion led to a high degree of engagement in the GSP process. The quality of the plan benefitted from the ad hoc TAG subcommittee that was formed to evaluate GDEs in the subbasin. The impact of this group extends beyond this GSP because their efforts helped to develop a GDE guidance document that is now being used by dozens of GSAs across the state. In addition, a special TAG public workshop was convened to discuss GDEs and solicit input from the public. TNC, many other environmental non-governmental organizations (NGOs), and federal resource agency provided feedback on the draft GSP, indicating strong engagement of environmental beneficial users. To ensure the plan is well implemented, we hope the GSA will continue to engage stakeholders to prioritize and develop management actions, as well as make plan improvements as data becomes available.

Interconnected Surface Waters (ISWs) – The GSP took steps towards identifying ISWs, however improvements should be made to identify environmental users of surface water, gaining and losing reaches, and/or to account for the spatial and temporal variations in stream depletions that are inherent with California's Mediterranean climate. These components are necessary to assess whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). Specifically, we disagree with the statements that there are limited groundwater elevation data for the semi-perched aquifer in the Oxnard Subbasin. These data, including well elevation data dating back to 1990, have been described in TNC's Technical Memorandum: Assessment of Groundwater Dependent Ecosystems for the Oxnard Subbasin Groundwater Sustainability Plan (Appendix K of the GSP). There have been previous efforts to assess the quantity and timing of ISWs and groundwater by other consultants working at or nearby the surface water bodies, such as shallow monitoring data and groundwater modeling at Naval Base Ventura County from site-specific groundwater investigations and surface water and groundwater monitoring data at the Santa Clara River estuary and lower floodplain. These data were utilized and included in TNC's Technical Memorandum. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 1,966 acres of potential GDEs occur in the GSA boundary. TNC developed the Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

We would like to applaud the GSA for appropriately identifying and mapping GDEs, and for considering GDEs throughout the plan as a beneficial user of groundwater. The GSP provided thoughtful characterization of GDEs in the Oxnard Subbasin, including using an earlier version of the statewide database of GDE indicators (iGDE v0.3.1; TNC, 2017) and TNC's GDE Guidance document (Rohde et al., 2018). In addition to the mapping of basin GDEs, it also includes an assessment of the hydrologic and ecological conditions of the potential GDEs.

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

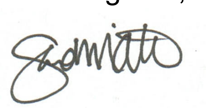
Water Budget – We would like to commend the GSP for including the groundwater demands of native vegetation and managed wetlands in the historical, current and projected water budgets.

Sustainable Management Criteria – We appreciate that the GSP includes and considers environmental beneficial uses and users of groundwater within the Sustainable Management Criteria. FCGMA Board of Directors adopted planning goals in 2015 that "Promote water levels that mitigate or minimize undesirable results (including pumping trough depressions, **surface water connectivity** [emphasis added], and chronic lowering of water levels)." Under current and known future conditions, as described in Section 3.3.6, the sustainability goal does not require inclusion of sustainability criteria for surface water connectivity. We agree this a reasonable position for the GSP *at this time*, given that the semi-perched aquifer is not currently managed for water supply. However, if future projects are envisioned to produce water from the semi-perched aquifer, sustainability criteria must be developed, since it is a principal aquifer, which is defined as "an aquifer that stores, transmits, and yields significant or economic quantities of groundwater to wells, springs, or surface water systems" [23 CCR § 351(aa)].

Monitoring Network – We would like to commend the GSP for developing a monitoring network that adequately characterizes the interaction of GDEs and other environmental beneficial users of surface water and groundwater. The GSP notes the lack of shallow groundwater monitoring wells in the semi-perched aquifer to monitor ISWs and GDEs along the Lower Santa Clara River, McGrath Lake, Ormond Beach and Mugu Lagoon, and potential GDEs along the Revolon Slough and Lower Calleguas Creek. We support the inclusion of monitoring wells within the potential GDEs to better assess the potential connectivity. A number of wells are in the vicinity of the GDEs and are already monitored by other agencies for specific remediation cases or regional studies. These should be included in the GSP. Making use of these existing monitoring wells provides long-term historical records, shares the burden of monitoring and provides important data at no cost to the GSA.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,



Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Attachment A

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Groundwater Sustainability Plan for the Oxnard Subbasin

The complete Final GSP for the Oxnard Subbasin, adopted December 13, 2019 as Resolution 19-05, was reviewed by TNC. TNC submitted comments on the Public Draft GSP on September 17, 2019. However, specific responses to comments on the Public Draft were not publicly available so we compared the Public Draft GSP to the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the FCGMA during the public comment period, and states whether or not they were addressed in the Final GSP [as green text in brackets]. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 1.8.2 Summary of Beneficial Uses and Users (pp. 1-45 to 1-46)]

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP identifies the primary environmental users in the Oxnard Subbasin as the identified GDEs described in Section 2.3.7, and includes aquatic habitat, in-channel wetlands, riparian forest, and coastal marshes. The GSA has included representation of environmental users on their Technical Advisory Group (TAG) in a special meeting on GDEs, and in GSP email and meeting notifications. Our suggestion is to explicitly list different types of beneficial uses and users of groundwater under each category. This would better clarify who these beneficial uses and users are in the basin. In regards to EBUs, we recommend that GDEs identified in the Basin Setting section (i.e., the lower Santa Clara River, McGrath Lake, Ormond Beach wetlands, Mugu Lagoon, Calleguas Creek, and Revolon Slough) be *specifically* listed, as well as the RWQCB surface water EBUs within GDEs listed in Section 2.3.7 (e.g., fish migration and wildlife habitat). The identified GDEs are inclusive of a variety of plant and animal species; some of which are recognized as state or federally threatened and endangered or special-status species and are designated critical habitat.

  We also recommend that the GSP specifically engage with the natural resource agencies, NOAA's National Marine Fisheries Service (NMFS), United States Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), as stakeholders since they are important parties representing the public trust. In particular, the efforts to address the habitat needs of endangered species such as the endangered Southern California Steelhead in the development of the Multiple Species Habitat Conservation Plan (HCP) is of particular importance. We suggest that NMFS be consulted to ensure the GSP addresses the ecological needs as represented by these public trust agencies.

- *[Our comment has been adequately addressed through GSP text changes. Thank you for making this change that promotes better delineation of native habitat and its environmental value.]* *In Table 1-8*, please revise the Land Use Category from "Vacant" to "Open Space". As noted in Section 1.3.2.3 - Historical, Current, and Projected Land Use and Section 1.6.1 – General Plans, this is a substantial acreage that is valued highly in Ventura County as open space, with ordinances such as the 1998 Save Open Space and Agricultural Resources ordinance. We need to do a better job of delineating open space and native habitat from the "vacant" category, as this devalues the environment and its water need.

Checklist Items 2 to 3 - Description of Plan Area [(23 CCR §354.8)

[Section 1.4.3 Operational Flexibility Limitations (p. 1-19 to 1-20)]

- *[Our comment has been adequately addressed through GSP text changes.]* A Multiple Species HCP prepared by United Water Conservation District (UWCD) specifies flow conditions at the Freeman Diversion to be constrained by the habitat requirements for the federally endangered Southern California steelhead (Oncorhynchus mykiss) in the Santa Clara River.

Checklist Items 6 and 7 - Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 2.2.3 Principal Aquifers and Aquitards (pp.2-6 to 2-7), with additional detail in Sections 1.3.2.1, 2.3.6, 2.3.7, 2.4.1.1, 2.4.2.5 and Appendix K]

- *[No response required. No changes to GSP text made.]* The Hydrogeologic Conceptual Model adequately describes the shallow groundwater that is interconnected with surface waters and GDEs. Basin-wide cross sections provided in Figures 2-3 and 2-4 include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. In the Oxnard Subbasin, the shallow groundwater unit and semi-perched aquifer, is connected to surface waters (e.g., Santa Clara River, Calleguas Creek, Revolon Slough, McGrath Lake, and the coastal wetlands at Ormond Beach and Mugu Lagoon). The semi-perched aquifer is not considered a principal aquifer due to its limited groundwater production (<50 AFY).

Checklist Items 8, 9 and 10 – Interconnected Surface Water (ISW) (23 CCR §354.16)

[Sections 1.3.2.1, 2.3.6, 2.3.7, 2.4.1.1, 2.4.2.5 and Appendix K (TNC GDE Tech Memo)]

- *[Our commend was not addressed. No changes to GSP text made.]* The Santa Clara River, Calleguas Creek, Revolon Slough, Mugu Lagoon, Ormond Beach, and McGrath Lake have all been identified as surface water bodies that may have a connection to the semi-perched aquifer in the Oxnard Subbasin. Qualitative statements are made regarding the interconnectedness, including gaining/losing reaches, and timing are provided, along with quantification, based on numerical modeling, of the recharge to groundwater from the Santa Clara River and Calleguas Creek.

We disagree with the qualifying statements that the "surface water bodies that may have a connection" and "However, groundwater elevation data for the semi-perched aquifer in the Oxnard Subbasin are extremely limited, with no monitoring sites near enough to surface water bodies to establish the extent of the connection between these surface water bodies and underlying groundwater." There have been previous efforts to assess the quantity and timing of interconnected surface water and groundwater by other consultants working at or nearby the surface water bodies, such as shallow monitoring data and groundwater modeling at Naval Base Ventura County from site-specific groundwater investigations and surface water and groundwater monitoring data at the Santa Clara River estuary and lower floodplain. These data, including well elevation data dating back to 1990, have been described in TNC's Technical Memorandum: Assessment of Groundwater Dependent Ecosystems for the Oxnard Subbasin Groundwater Sustainability Plan (Appendix K). TNC's assessment of these reports indicate that the water elevation data and analyses corroborate the conceptual model that groundwater levels in the semi-perched aquifer relatively constant with a seasonal cyclical behavior, although there has been a downward trend with the recent (2011-16) drought. These reports and data provide estimates of quantity and timing of groundwater - surface water interactions. The GSA should review said reports and data and revise these statements to be definitive statements of the connections of surface water and groundwater.

<u>Checklist Items 11 to 20 - Identification, Mapping and Description of GDEs (23 CCR §354.16)</u>

[Section 2.3.7 Groundwater-Dependent Ecosystems (pp. 2-43 – 2-46) and Appendix K]

- *[No response required. No changes to GSP text made.]* GDEs have been identified and mapped during the GSP development process using an earlier version of the statewide database of GDE indicators (iGDE v0.3.1; TNC, 2017) and TNC's GDE Guidance document (Rohde et al., 2018). This evaluation is described in Appendix K, with a brief summary in Section 2.3.7. In addition to the mapping of basin GDEs, it also includes both an assessment of the hydrologic and ecological conditions of the GDEs and potential GDEs.

[Executive Summary (p. 1-1) and Section 1.1 Purpose of the Groundwater Sustainability Plan (p.1-2)]

- *[No response required. No changes to GSP text made.]* While we support the position that "Depletions of interconnected surface water have not occurred historically in the Subbasin, because the Groundwater-Dependent Ecosystems (GDEs) in the Subbasin are supported by shallow groundwater flows that are generally separated and disconnected from the primary groundwater aquifers," we would like to make this clear that historical conditions represent the time period referenced by SGMA – since the 1980s. As noted in Section 2.2.3, once agriculture grew in the Oxnard Subbasin, groundwater levels in the semi-perched aquifer were lowered using the agricultural tile drains (installed in the 1900s) for drainage of irrigated water from the agricultural fields.

Checklist Items 21 and 22 - Water Budget (23 CCR §354.18)

[Section 2.4 Water Budget]

- *[No response required. No changes to GSP text made.]* The water budget now includes the semi-perched aquifer and the surface hydrologic components of the semi-perched aquifer, including the groundwater-surface water exchanges with the Santa Clara River and the Calleguas Creek and natural vegetation evapotranspiration (ET). We appreciate the separate inclusion of the semi-perched aquifer water budget.

Checklist Items 23 to 25 - Sustainability Goal (23 CCR §354.24)

[Section 3.1 Introduction to Sustainable Management Criteria (p. 3-1)]

- *[No response required. No changes to GSP text made.]* FCGMA Board of Directors adopted planning goals in 2015 that "Promote water levels that mitigate or minimize undesirable results (including pumping trough depressions, **surface water connectivity** [emphasis added], and chronic lowering of water levels)."

  Under current and known future conditions, as described in Section 3.3.6, the sustainability goal does not require inclusion of sustainability criteria for surface water connectivity. We agree this as reasonable position for the GSP *at this time*, given that the semi-perched aquifer is not managed for water supply. However, if future projects are envisioned to produce water from the semi-perched aquifer, sustainability criteria should be developed.

Checklist Items 30 to 46 - Undesirable Results (23 CCR §354.26)

[Section 3.3.6 Depletions of Interconnected Surface Water (p. 3-10 - 3-11)]

- *[No response required. No changes to GSP text made.]* The GSP clearly states: "The undesirable result associated with depletion of interconnected surface water in the Oxnard Subbasin is loss of groundwater-dependent ecosystem (GDE) habitat." We applaud this clear recognition of GDEs as an important beneficial use that must be protected. We also agree with further statements that 1) undesirable results are not currently occurring, 2) groundwater elevation monitoring will continue to be monitored in the semi-perched aquifer, and 3) if future projects involve the use of the semi-perched aquifer, then "depletion of interconnected surface water is possible, and significant and unreasonable impacts may occur." While we agree that "Reevaluation of the effects on existing and potential GDEs should be conducted in conjunction with the project approval process for any such future projects," we urge stronger language to specifically state sustainability criteria will be developed at that future time.

Checklist Items 27 to 29 - Minimum Thresholds (23 CCR §354.28)

[Section 3.4.6 Minimum Thresholds – Depletions of Interconnected Surface Water (pp. 3-19 to 3-20)]

- *[No response required. No changes to GSP text made.]* We applaud the language recognizing that future projects may have a potential impact on ISWs and GDEs, and that "if projects that produce groundwater from the semi-perched aquifer are implemented, the need for specific water level minimum thresholds in the semi-perched aquifer should be reevaluated".

  This section defines minimum thresholds due to salinity front as the modeling shows Upper Aquifer System (UAS) levels support the groundwater elevations in the semi-perched aquifer. This is confusing as it seems like the recharge is predominantly downwards from the semi-perched aquifer to the UAS. It is unclear how the UAS is influencing the salinity front in the semi-perched aquifer.

Checklist Item 26 - Measurable Objectives (23 CCR §354.30)

[Section 3.5.6 Measurable Objectives – Depletions of Interconnected Surface Water (pp. 3-26 to 3-27)]

- *[We applaud the inclusion of the suggestion listed in our comments.]* A measurable objective for ISWs in the semi-perched aquifer is set to address seawater intrusion. We recommend adding a statement, as is done in Section 3.4.6, that "if projects that produce groundwater from the semi-perched aquifer are implemented, specific water level measurable objectives in the semi-perched aquifer should be developed".

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

[Section 4.3.6 Depletions of Interconnected Surface Water (p. 4-10)]

- *[Our comment was not addressed. No changes to GSP text made.]* We recommend including remote sensing vegetative indices as a low-cost approach to monitor baseline conditions of GDEs. TNC's free online tool, GDE Pulse, allows GSAs a way to assess changes in GDE health using remote sensing data sets; specifically, the Normalized Difference Vegetation Index (NDVI), which is a satellite-derived index that represents the greenness of vegetation and Normalized Difference Moisture Index (NDMI), which is a satellite-derived index that represents water content in vegetation.

[Section 4.6.5 Shallow Groundwater Monitoring near Surface Water Bodies and GDEs (p. 4-15)]

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP notes the lack of shallow groundwater monitoring wells in the semi-perched aquifer that can be used to monitor ISWs and GDEs along the Lower Santa Clara River, McGrath Lake, Ormond Beach and Mugu Lagoon, and potential GDEs along the Revolon Slough and Lower Calleguas Creek in the Subbasin. We support the inclusion of monitoring wells within the potential GDEs to better assess the potential connectivity. A number of wells are in the vicinity of the GDEs and are monitored by other agencies for specific remediation cases or regional studies. These should be included in the GSP. It is to the benefit of the GSA to make use of these existing monitoring wells as they provide long-term historical records and are already monitored by other agencies and are available at no cost to the GSA. The data have been made available for the GSP and it is recommended that monitoring agreements be put in place to receive ongoing data on these wells and ensure the long-term monitoring continues. In particular, we suggest the following wells to serve as representative monitoring wells for each GDE in order to monitor impacts caused by depletions of ISWs (Figures 6-9, Appendix K):

GDE	**Well**
Lower Santa Clara River	2N22W30A03S
McGrath Lake	GW-3
Ormond Wetlands	01N22W27G04S
Mugu Lagoon	MW6-6A

[Section 4.6.6 Surface Water: Flows in Agricultural Drains in the Oxnard Plain (pp. 4-15 to 4-16)]

- *[Our comment was not addressed. No changes to GSP text made.]* We would also recommend that surveying the water surface elevation in the drains, as they should be easy to measure, provide calibration head values for the numerical model and be a good indication of the semi-perched aquifer elevations.

Checklist Items 50 and 51 - Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Section 5.8 Management Action No. 2 – Water Market Pilot Program (pp. 5-17 to 5-18)]

- *[No response required. No changes to GSP text made.]* The GSP indicates that significant reductions in groundwater extractions will be needed to avoid undesirable results. These reductions may have serious impacts on existing extractors. We support development and implementation of a well-designed water market that will incentivize conservation and provide flexibility for pumpers in meeting the objectives of the GSP. The water market must have rules that prevent negative impacts to other beneficial users such as the environment and Disadvantaged Communities.

Attachment C

Freshwater Species Located in the Oxnard Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Oxnard Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[2]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the CDFW's BIOS[3] as well as on TNC's science website[4].

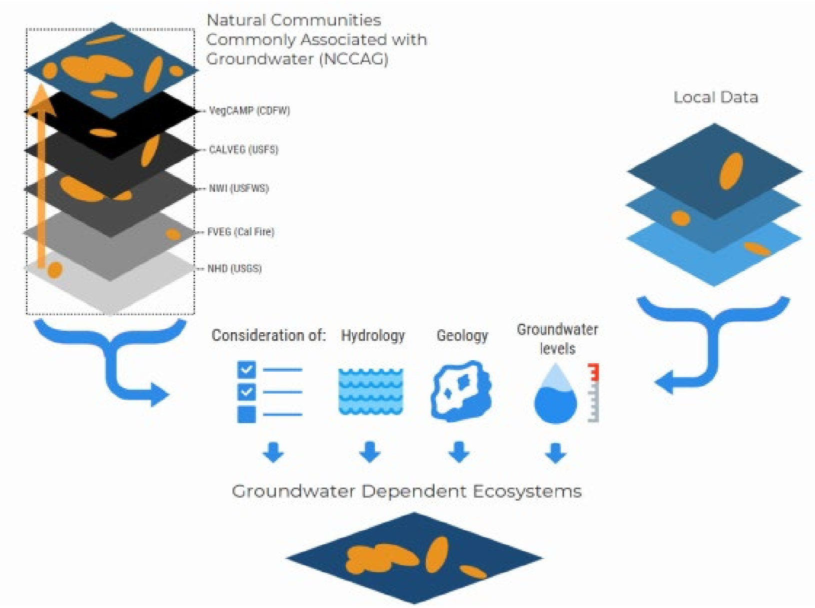
IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[5] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[6]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.

[5] *NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/*

[6] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf



The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[7]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[8] on the Groundwater Resource Hub[9], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may

---

[9] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

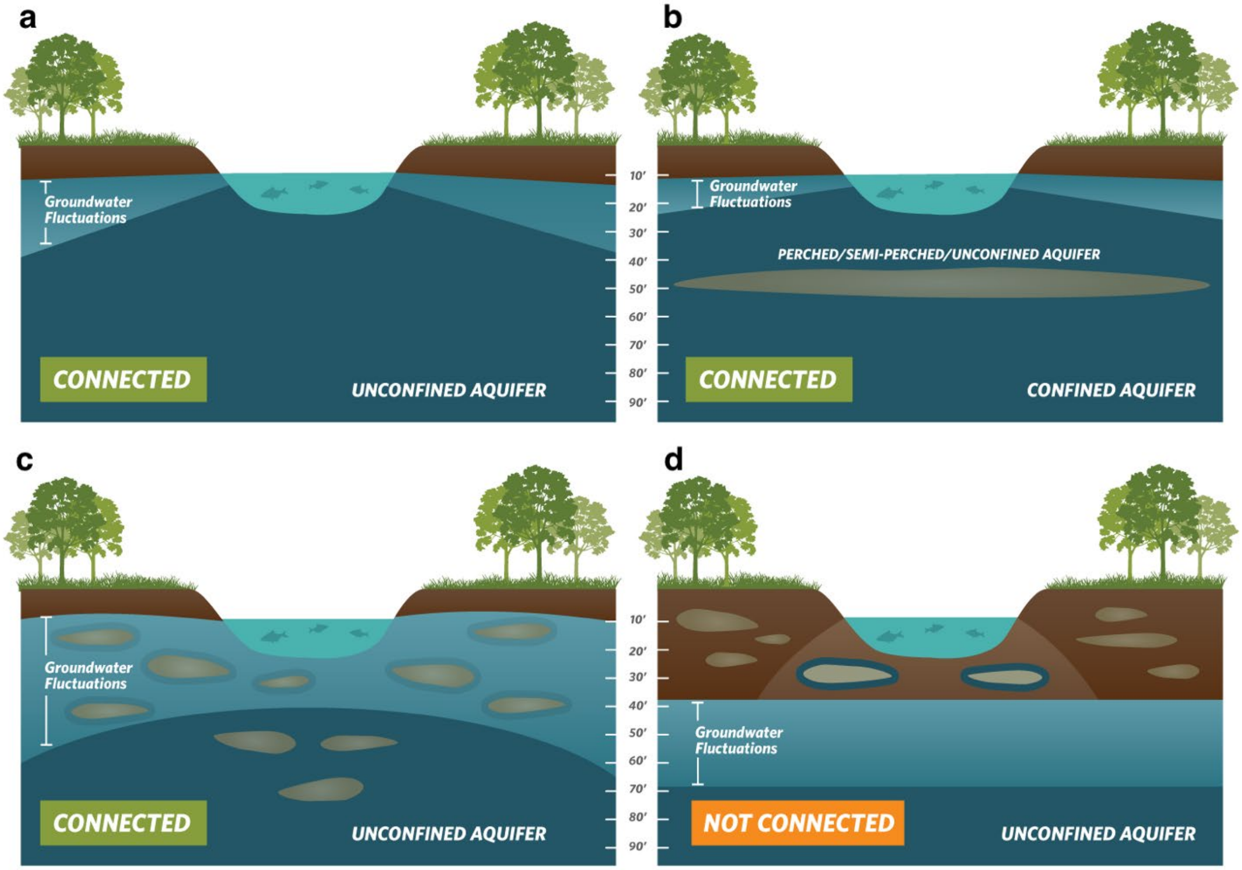

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[10] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[11] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[12] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[13]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

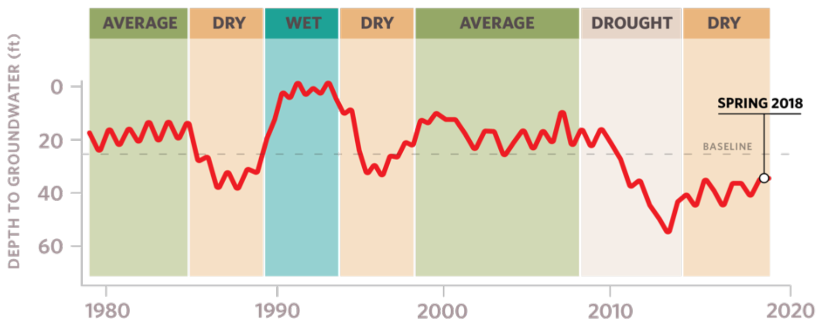

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

---

[11] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[12] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[13] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[14], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

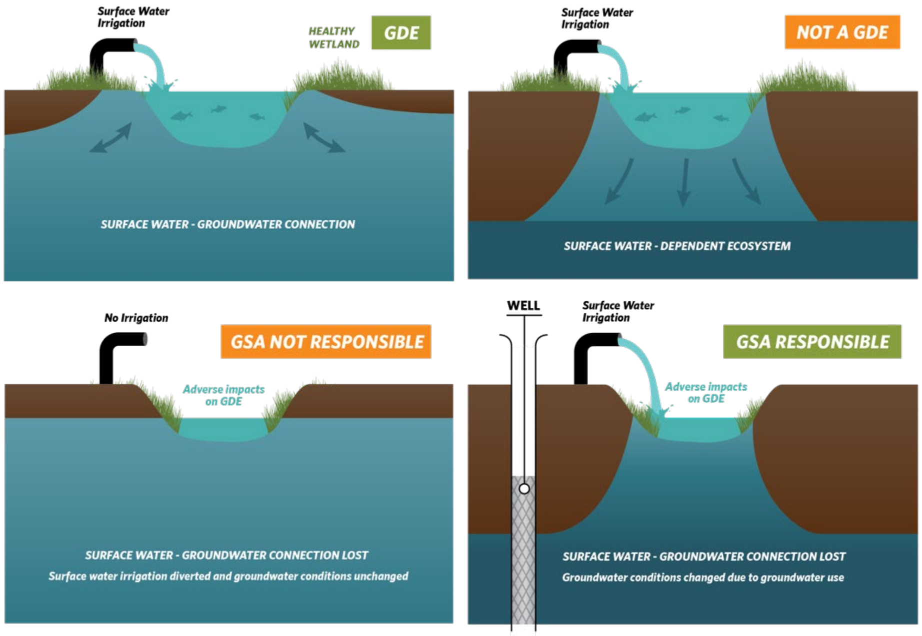

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[14] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

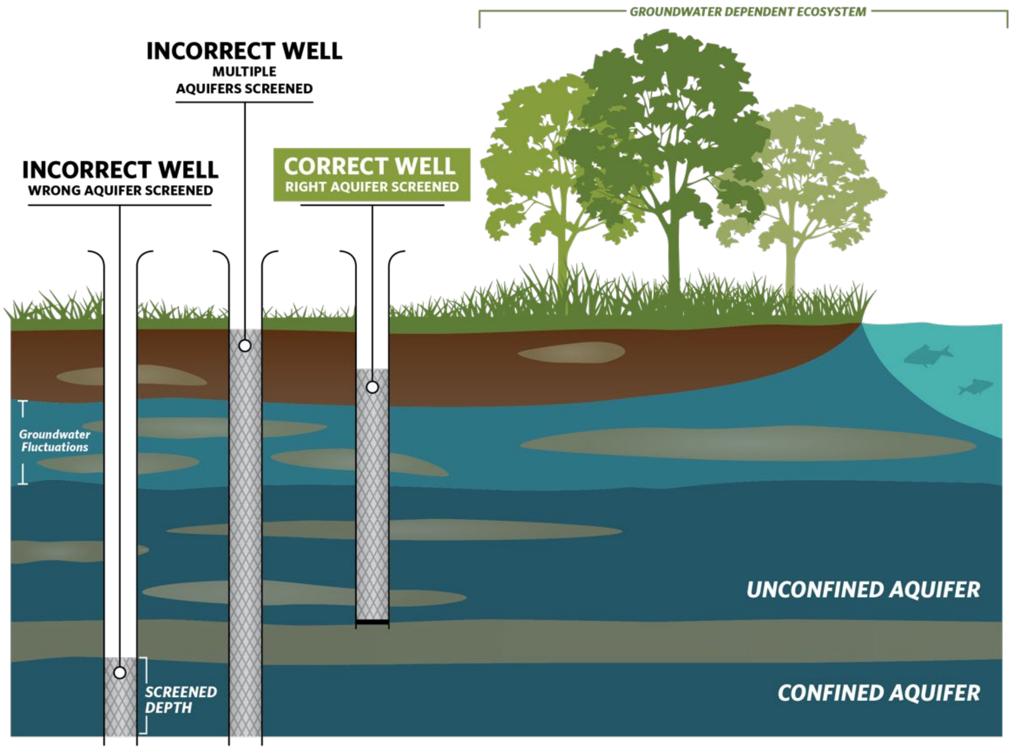

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[15] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

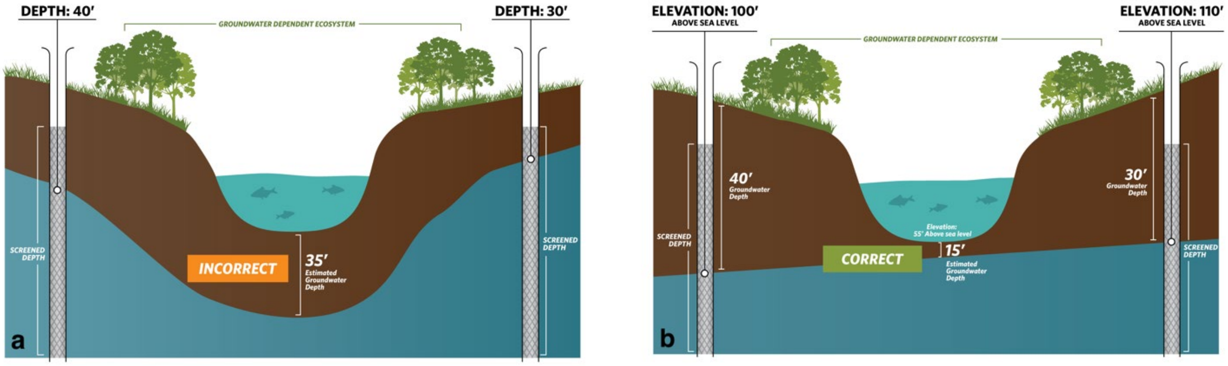

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

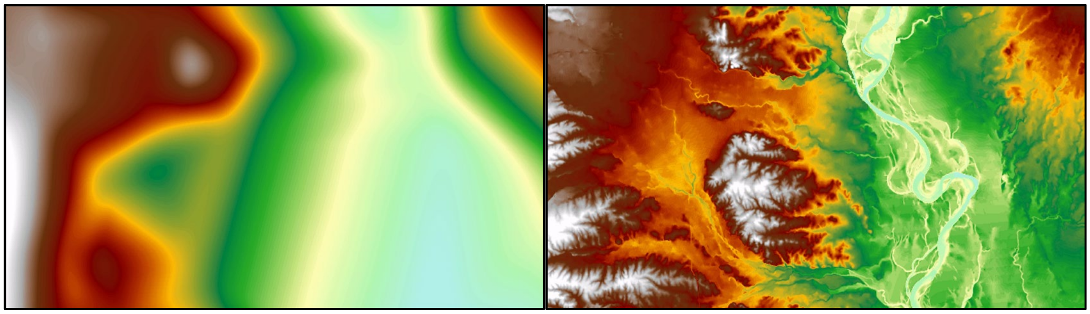

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[15] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Attachment E

GDE Pulse

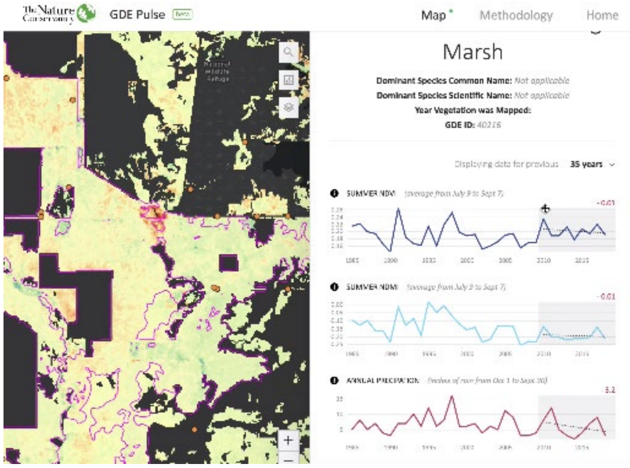
The Nature Conservancy
Protecting nature. Preserving life.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[16]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[17]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[18]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[19]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[20] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Pleasant Valley Basin Groundwater Sustainability Plan (GSP)

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Fox Canyon Groundwater Management Agency's Pleasant Valley Basin Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be sufficient in addressing environmental beneficial uses and users.

We would like to compliment the GSA for their treatment of environmental beneficial users in the GSP. We believe the GSA sufficiently addressed environmental beneficial users in this first GSP submission. In the spirit of continual improvement embedded in SGMA, we would like to offer the following input as areas for improvement in the next version of the GSP.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We would like to commend the GSA for incorporating our feedback, indicating strong engagement of environmental beneficial users. In addition, we would like to commend the GSA for including an environmental representative, a TNC staff member, on the Technical Advisory Group (TAG) throughout the GSP development. This inclusion led to a high degree of engagement in the GSP process. The quality of the plan benefitted from the ad hoc TAG subcommittee that was formed to evaluate GDEs in the subbasin. The impact of this group extends beyond this GSP because their efforts helped to develop a GDE guidance document that is now being used by dozens of GSAs across the state. In addition, a special TAG public workshop was convened to discuss GDEs and solicit input from the public. TNC, many other environmental non-governmental organizations (NGOs), and federal resource agency provided feedback on the draft GSP, indicating strong engagement of environmental beneficial users. To ensure the plan is well implemented, we hope the GSA will continue to engage stakeholders to prioritize and develop management actions, as well as make plan improvements as data becomes available.

Interconnected Surface Waters - We are pleased to see that the GSP took steps to identify and map ISWs. Arroyo Las Posas, Conejo Creek, and Calleguas Creek have all been identified as surface water bodies that may have a connection to the Shallow Alluvial Aquifer in the Pleasant Valley Basin. It is recognized that Arroyo Las Posas is ephemeral in the Pleasant Valley Basin and is likely to be a disconnected losing stream, and Conejo Creek and Calleguas Creek are likely perennial due to wastewater treatment discharges. Numerical modeling estimates of annual quantification of recharge to groundwater from Arroyo Las Posas, Conejo Creek, and Calleguas Creek are provided in Section 2.3.6. However, while the model results list net recharge to groundwater via stream loss, the discussion in Sections 2.3.6 and 2.3.7 indicates there is insufficient knowledge to build a conceptual model of the extent of losing and gaining reaches. ISWs are defined as "surface water that is hydraulically connected *at any point* by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted." (23 CCR §351(o)), (emphasis added) "At any point" has both a spatial and temporal component. Even short durations of interconnection between groundwater and surface water can be crucial for surface water flow and support of wetlands. Until a disconnection can be proven, we recommend that potential ISWs be included in the plan.

Groundwater Dependent Ecosystems – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 301 acres of potential GDEs occur in the GSA boundary. TNC developed the Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

We would like to applaud the GSA for appropriately identifying and mapping GDEs, and for considering GDEs throughout the plan as a beneficial user of groundwater. The GSP provided

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

thoughtful characterization of Wetland GDEs and Vegetative GDEs in the Pleasant Valley Basin area, including using an earlier version of the statewide database of GDE indicators (iGDE v0.3.1; TNC, 2017) and TNC's GDE Guidance document (Rohde et al., 2018). In addition to the mapping of basin GDEs, it also includes 1) an assessment of the hydrologic and ecological conditions of the potential GDEs; and 2) TNC's comment letter to the draft GSP (as Appendix A-5 to the GSP), which includes the list of freshwater species included in Attachment C of this letter.

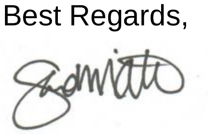
Water Budget – We would like to commend the GSP for including the groundwater demands of native vegetation and managed wetlands in the historical, current and projected water budgets.

Sustainable Management Criteria – We appreciate that the GSP includes and considers environmental beneficial uses and users of groundwater within the Sustainable Management Criteria. Fox Canyon Groundwater Management Agency (FCGMA) Board of Directors adopted planning goals in 2015 that "Promote water levels that mitigate or minimize undesirable results (including pumping trough depressions, **surface water connectivity** [emphasis added], and chronic lowering of water levels)." Under current and known future conditions, as described in Section 3.3.6, the sustainability goal does not require inclusion of sustainability criteria for surface water connectivity. We agree with this position given the uncertainty regarding the depths to groundwater as described in Section 2.3.3 and 2.3.7. Nevertheless, the criteria should be reevaluated in the future if future projects confirm the linkage between GDEs and ISWs or cause undesirable results.

Monitoring Network – We would like to commend the GSP for developing a monitoring network that adequately characterizes the interaction of GDEs and other environmental beneficial users of surface water and groundwater. The GSP notes the lack of shallow groundwater monitoring wells in the Shallow Alluvial Aquifer that can be used to monitor ISWs and GDEs along the Arroyo Las Posas. We do not think this is necessary for the Arroyo Las Posas. We recommend further investigation of the water level records in the younger alluvium that are available from shallow wells associated with groundwater remediation cases and made available on GeoTracker. If these water level records can demonstrate the groundwater connection, or lack thereof, then the data gap regarding connectivity can be closed.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,



Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Pleasant Valley Basin Groundwater Sustainability Plan
Comments based on Draft and Final GSPs

The complete Final GSP for the Pleasant Valley Basin, adopted December 13, 2019 as Resolution 19-05, was reviewed by TNC. TNC submitted comments on the Public Draft GSP on September 17, 2019. However, specific responses to comments on the Public Draft were not publicly available, so we compared the Public Draft GSP to the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the Fox Canyon Groundwater Management Agency during the public comment period, and states whether or not they were addressed in the Final GSP [as green text within brackets]. Any change to the text of our draft comments will be displayed as red text. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 1.8.2 Summary of Beneficial Uses and Users (pp. 1-45 to 1-46)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GSP identifies the primary EBUs in the Pleasant Valley Basin as the willow/mulefat riparian scrub and arundo vegetation communities found along the banks of Conejo Creek, Calleguas Creek, lower Arroyo Las Posas, and Conejo Creeks. The degree to which these ecosystems use groundwater versus percolating surface water is uncertain. The GSA has included representation of environmental users on their Technical Advisory Group (TAG) in a special meeting on GDEs, and in GSP email and meeting notifications. We recommend that the GSP specifically list the natural resource agencies, such as the National Marine Fisheries Service, United States Fish and Wildlife Service (USFWS), and California Department of Fish and Wildlife (CDFW), as stakeholders since they are important parties representing the public trust. In addition, both the CDFW and the USFWS have attended the special TAG GDE meeting.

[Section 1.3.2.3 Historical, Current and Projected Land Use (Table 1-8) (p. 1-51)]

- *[Our comment has been adequately addressed through changes in the GSP text. The text in Table 1-8 was revised from Vacant to Open Space.]* Please revise the Land Use Category from "Vacant" to "Open Space". As noted in Section 1.3.2.3 - Historical, Current, and Projected Land Use and Section 1.6.1 – General Plans, this is a substantial acreage that is valued highly in Ventura County as open space, with ordinances such as the 1998 Save Open Space and Agricultural Resources ordinance. We need to do a better job of delineating open space and native habitat from the "vacant" category, as this devalues the environment and its water need.

Checklist Items 2 and 3 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8)

[Section 1.4.2 Operational Flexibility Limitations (pp. 1-19 to 1-20)]

- *[No changes to GSP text made.]* A Multiple Species Habitat Conservation Plan (HCP) prepared by United Water Conservation District (UWCD) specifies flow conditions at the Freeman Diversion to be constrained by the habitat requirements for the federally endangered Southern California steelhead (*Oncorhynchus mykiss*) in the Santa Clara River. These flow requirements and how may be affected and/or addressed by this GSP needs to be flushed out in the document.

Checklist Items 6 and 7 - Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 2.2.4 Principal Aquifers and Aquitards (pp. 2-6 to 2-7), with additional detail in Sections 1.3.2.1, 2.3.1.1, 2.3.6, 2.3.7, 2.4.1.1, 2.4.2.5, and Appendix K]

- *[No changes to GSP text made.]* Description & cross-sections are contradictory in presenting the extent of the Shallow Alluvial Aquifer. Also, it is not clear where the semi-perched and Shallow Alluvial aquifers are located in the discussion. Aerial extent maps should be included, and it made clear whether these are or are not principal aquifers.
- *[No changes to GSP text made.]* Section 2.2.4 describes the Shallow Alluvial Aquifer that is interconnected with surface waters (Arroyo Las Posas, Conejo Creek, and Calleguas Creek) and potential GDEs. The basin-wide cross sections provided in Figures 2-3 and 2-5 include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic, though the representation doesn't match the text language in Section 2.3.1.1, which states "The Shallow Alluvial Aquifer comprises the **recent alluvial deposits** [emphasis added] that line Arroyo Las Posas, Arroyo Santa Rosa, Conejo Creek, and Calleguas Creek in the PVB". Also Figure 2-4 does not indicate presence of the Shallow Alluvial Aquifer in this area. Figure 2-2 shows the recent alluvium along Conejo Creek and lower part of Calleguas Creek, but the placement of the Shallow Alluvial Aquifer in the cross-section A-A' in Figure 2-3 doesn't quite match up. Including the locations of the Conejo and Calleguas Creeks would help clarify the understanding. It is also unclear where the semi-perched aquifer exists within the Pleasant Valley Basin. Neither the Shallow Alluvial Aquifer nor the semi-perched aquifer are considered principal aquifers in the Pleasant Valley Basin.

Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16); and Identification of ISWs is a required element of Current and Historical Groundwater Conditions (23 CCR §354.16)

[Sections 1.3.2.1, 2.3.6, 2.3.7, 2.4.1.1]

- *[No changes to GSP text made.]* Arroyo Las Posas, Conejo Creek, and Calleguas Creek have all been identified as surface water bodies that may have a connection to the Shallow Alluvial Aquifer in the Pleasant Valley Basin. Arroyo Las Posas is ephemeral in the Pleasant Valley Basin and is likely to be a disconnected losing stream, and Conejo Creek and Calleguas Creek are perennial due to wastewater treatment discharges. Numerical modeling estimates of annual recharge to groundwater from Arroyo Las Posas, Conejo Creek, and Calleguas Creek are provided in Section 2.3.6. However, while the model results list net recharge to groundwater via stream loss, the discussion in Sections 2.3.6 and 2.3.7 indicates there is insufficient knowledge to build a conceptual model of the extent of losing and gaining reaches.

Checklist Items 11 to 20 - Identification, Mapping and Description of GDEs (23 CCR §354.16)

[Section 2.3.7 Groundwater-Dependent Ecosystems (pp. 2-25 to 2-27)]

- *[We applaud the thoughtful characterization of Wetland and Vegetative GDEs in the Pleasant Valley Basin area.]* GDEs have been identified and mapped during the GSP development process using an earlier version of the statewide database of GDE indicators (iGDE v0.3.1; TNC, 2017) and TNC's GDE Guidance document (Rohde et al., 2018). In addition to the mapping of basin GDEs, it also includes both an assessment of the hydrologic and ecological conditions of the potential GDEs. Given the uncertainty regarding the depths to groundwater within these areas, the ecosystems are appropriately considered potential GDEs, with future monitoring needs identified to assess the degree to which existing habitat is reliant on groundwater.

Checklist Items 21 and 22 - Water Budget (23 CCR §354.18)

[Section 2.4 Water Budget (p. 2-28)]

- *[We applaud the thoughtful characterization of the water budget, and inclusion of natural systems.]* The water budget includes the natural system surface hydrology components, including the surface water recharge from the Arroyo Las Posas, Conejo Creek, and Calleguas Creek and natural vegetation evapotranspiration (ET) along these riparian systems. These were modeled using the UWCD numerical model.

Checklist Items 23 to 25 - Sustainability Goal (23 CCR §354.24)

[Section 3.1 Introduction to Sustainable Management Criteria (p. 3-2)]

- *[No response required. No changes to GSP text made.]* The Fox Canyon Groundwater Management Agency (FCGMA) Board of Directors adopted planning goals in 2015 that "Promote water levels that mitigate or minimize undesirable results (including pumping trough depressions, **surface water connectivity** [emphasis added], and chronic lowering of water levels)." However, under the current and known future conditions described in Section 3.3.6, the sustainability goal does not include sustainability criteria for surface water connectivity.

Checklist Items 30 to 46 - Undesirable Results (23 CCR §354.26

[Section 3.3.6 Depletions of Interconnected Surface Water (pp. 3-12 to 3-13)]

- *[We applaud the clear recognition of GDEs as an important beneficial use that must be protected.]* The GSP clearly states: "The undesirable result associated with depletion of interconnected surface water in the PVB is loss of groundwater-dependent ecosystem (GDE) habitat." We applaud this clear recognition of GDEs as an important beneficial use that must be protected. We also agree with further statements that 1) undesirable results are not currently occurring, 2) linkage between groundwater and the potential GDEs must be established, and 3) if future projects involve the use of the Shallow Alluvial Aquifer then "depletion of interconnected surface water may be possible, and significant and unreasonable impacts may occur."

Checklist Items 27 to 29 - Minimum Thresholds (23 CCR §354.28)

[Section 3.4.6 Minimum Thresholds – Depletions of Interconnected Surface Water (p. 3-20)]

- *[Our comment has been adequately addressed through changes in the GSP text.]* We agree that no minimum thresholds need to be proposed at this time. The statement that Calleguas Creek and Conejo Creek are ephemeral streams need to be corrected as they are perennial within PBV. We would also request that the statement "depletion of interconnected surface water in the PVB is not currently occurring and is unlikely to occur in the future" be struck. Earlier text in Section 2.3.7 makes it clear that this is not known. Rather, we recommend language like that from the Oxnard Subbasin GSP: "if projects that produce groundwater from the Shallow Alluvial Aquifer are implemented, the need for specific water level minimum thresholds in it should be reevaluated".

Checklist Item 26 - Measurable Objectives (23 CCR §354.30

[Section 3.5.6 Measurable Objectives – Depletions of Interconnected Surface Water (p. 3-25)]

- *[Our comment has been adequately addressed through GSP text changes.]* We agree that no minimum thresholds need to be proposed at this time. The statement that Calleguas Creek and Conejo Creek are ephemeral streams needs to be corrected as they are perennial within PBV. We would also request that the statement "depletion of interconnected surface water in the PVB is not currently occurring and is unlikely to occur in the future" be struck. Earlier text in Section 2.3.7 makes it clear that this is not known and may be an identifiable data gap. Rather, we recommend language like that from the Oxnard Subbasin GSP: "if projects that produce groundwater from the Shallow Alluvial Aquifer are implemented, the need for specific water level minimum thresholds in it should be reevaluated".

Checklist Items 47, 48 and 49 - Monitoring Network (23 CCR §354.34)

[Section 4.3.6 Depletions of Interconnected Surface Water (p. 4-9)]

- *[No changes to GSP text made.]* We recommend including remote sensing vegetative indices as a low cost approach to monitor baseline conditions of GDEs. TNC's free online tool, GDE Pulse (Attachment E), allows GSAs a way to assess changes in GDE health using remote sensing data sets; specifically, the Normalized Difference Vegetation Index (NDVI), which is a satellite-derived index that represents the greenness of vegetation and Normalized Difference Moisture Index (NDMI), which is a satellite-derived index that represents water content in vegetation.

[Section 4.6.5 Shallow Groundwater Monitoring near Surface Water Bodies and GDEs (p.4-15)]

- *[No changes to GSP text made.]* The GSP notes the lack of shallow groundwater monitoring wells in the Shallow Alluvial Aquifer that can be used to monitor ISWs and GDEs along the Arroyo Las Posas, Conejo Creek, and Calleguas Creek. We do not think this is necessary for the Arroyo Las Posas. We recommend further investigation of the water level records in the younger alluvium that are available from shallow wells associated with groundwater remediation cases and made available on GeoTracker. If these water level records can demonstrate the groundwater connection, or lack thereof, then the data gap regarding connectivity can be closed. This could be very useful given that there is limited funding available to install new monitoring wells. ~~and this is currently a low priority given that the Shallow Alluvial Aquifer is not a principal aquifer.~~

[Section 4.6.6 Surface Water: Flows in Agricultural Drains in the PVB (p. 4-15)]

- *[No changes to GSP text made.]* We recommend surveying the water surface elevation in the drains, as they should provide easy to measure, calibration head values for the numerical model and good indication of the semi-perched aquifer elevations.

Checklist Items 50 and 51 - Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Section 5 Projects and Management Actions]

- *[No response required. No changes to GSP text made.]* Section 2.3.8, Potential Recharge Areas, identifies potential future recharge areas that have the most favorable soil recharge rates. These are along the Arroyo Las Posas, Conejo Creek, and Calleguas Creek. Consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity as well as provide environmental benefits or benefits to disadvantaged communities. TNC recommends the GSA look for environmental partners to co-develop such multi-benefit projects that benefit supply and environment; our perspective is that additional funding can be gained from such projects.

Attachment C

Freshwater Species Located in the Pleasant Valley Basin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Pleasant Valley Basin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[2]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[3] as well as on The Nature Conservancy's science website[4].

Scientific Name	Common Name	Legally Protected Species		
		Federal	State	Other

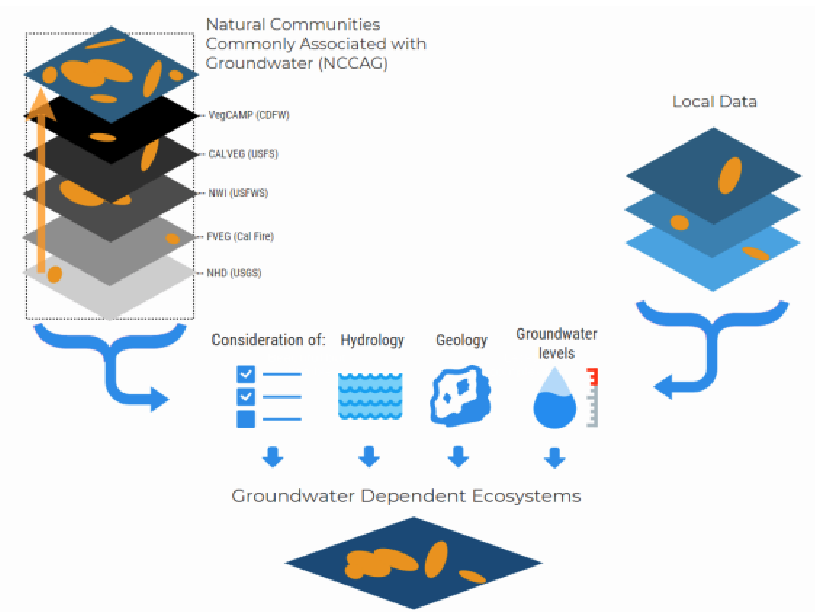
July 2019

IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[5] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[6]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[5] *NC Dataset Online Viewer:* *https://gis.water.ca.gov/app/NCDatasetViewer/*

[6] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[7]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[8] on the Groundwater Resource Hub[9], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

[9] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

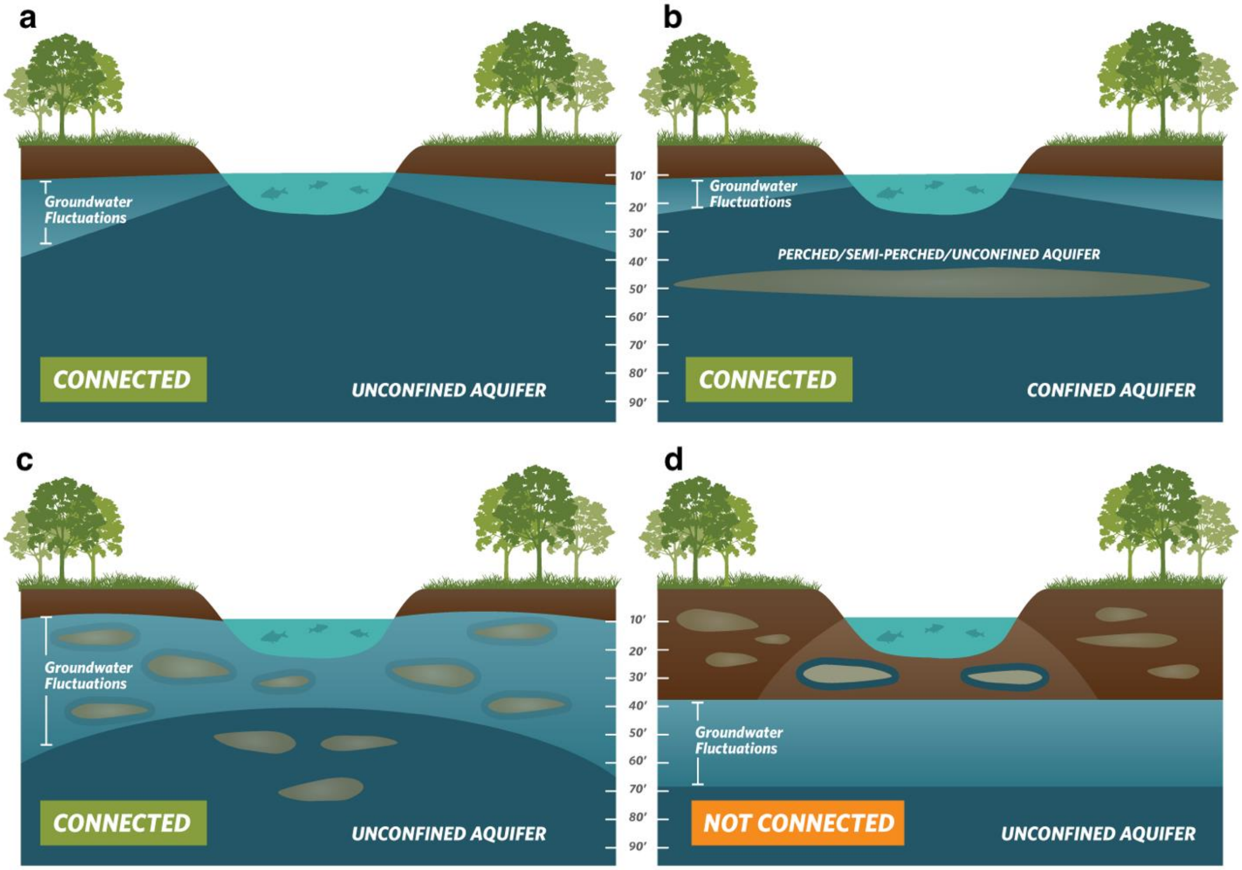

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[10] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[11] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[12] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[13]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

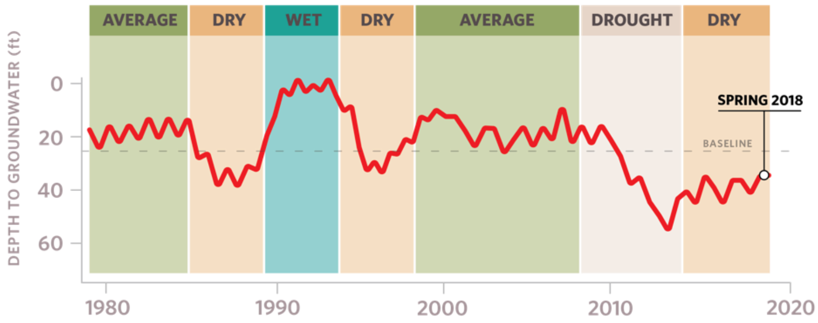

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[10] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[11] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[12] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[13] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[14], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

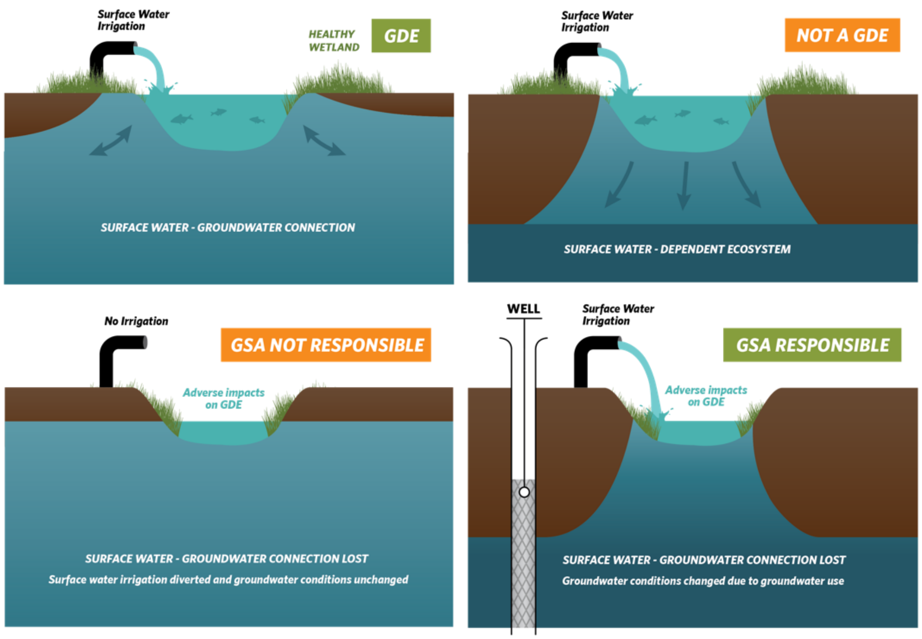

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[14] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

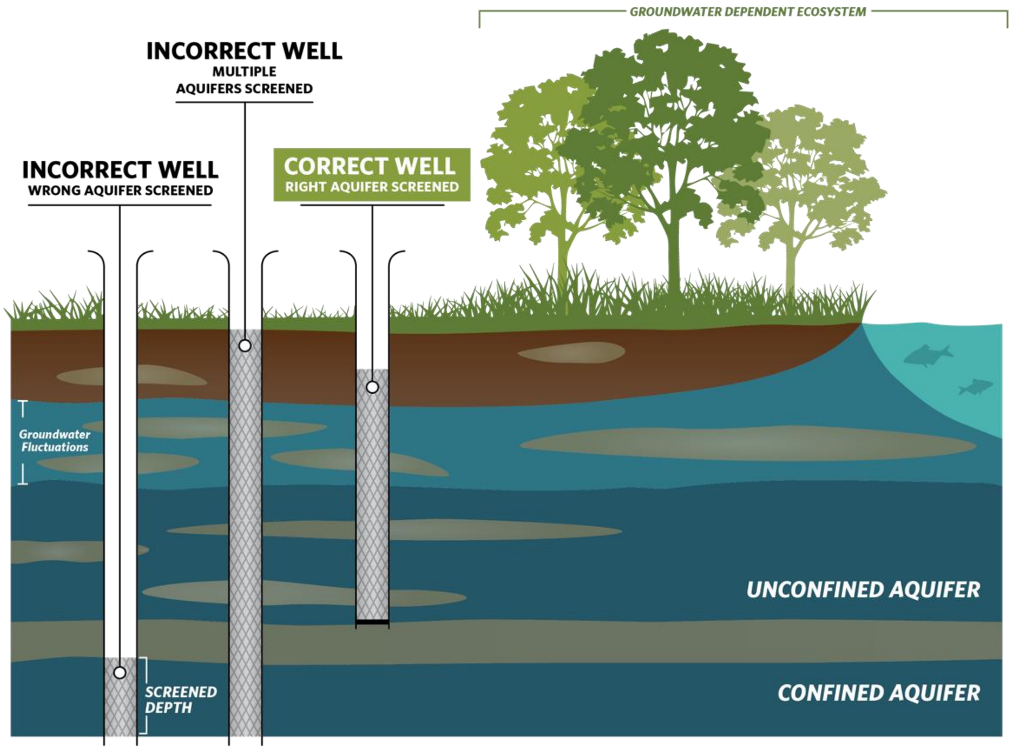

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[15] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

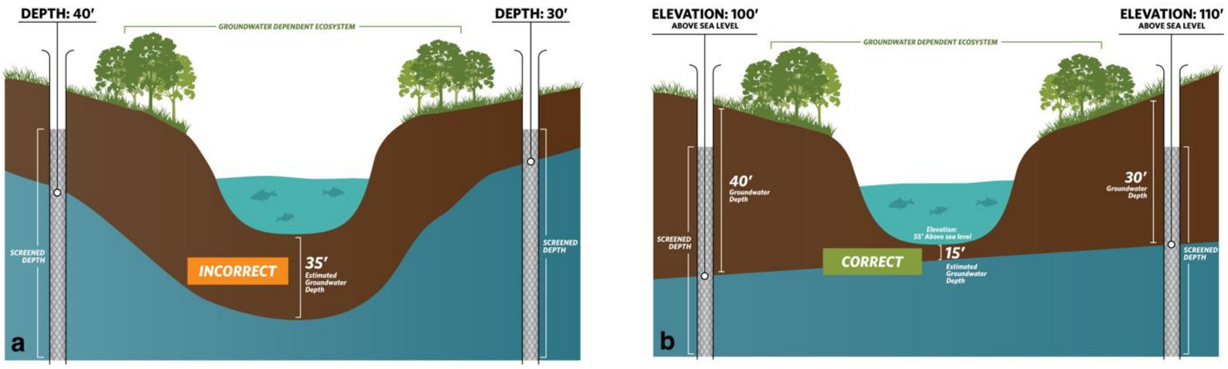

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

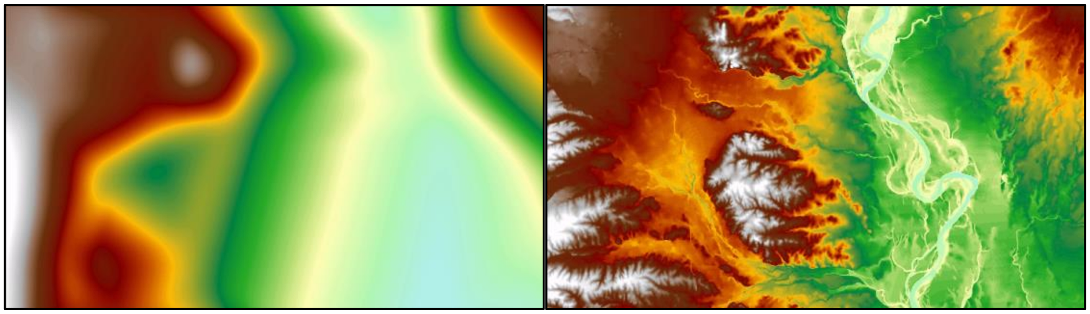

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

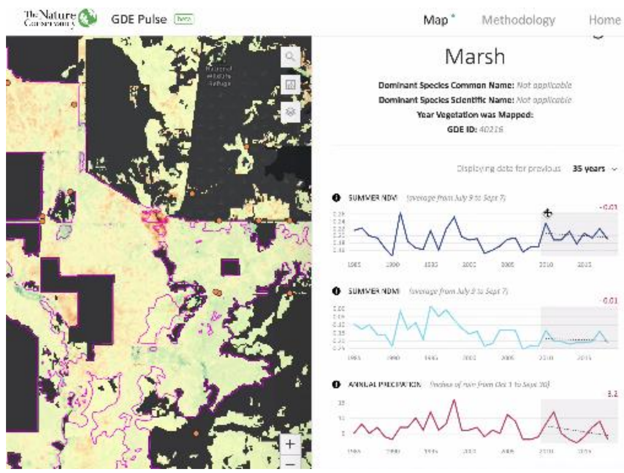
GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[16]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[17]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[18]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[19]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[20] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Central Kings Groundwater Sustainability Plan (GSP), Kings Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Central Kings Groundwater Sustainability Agency's (GSA's) Central Kings Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides a map and method summary of potential ISWs.

<u>Our Key Considerations</u>

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as only 1 out of 56 of our comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

<u>TNC recommendation</u>: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were excluded based on lack of continuous saturation between surface water and groundwater. This justification of automatic removal is incorrect and inconsistent with the definition of ISWs. The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. Our analysis of groundwater levels between 2011 and 2018 indicate the Kings River from Sanger to an area downstream from Reedley is likely ISW. Therefore, potential ISWs are not being managed in the GSP.

<u>Map and Assessment of potential ISWs</u>:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the Central Kings GSP, 8.2 river miles are gaining, 5.9 are losing, and the rest are uncertain or likely disconnected. Attachment F contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on surface water-groundwater interconnectivity and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 991 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not to adequately identify, map and consider GDEs. We believe that this does not meet plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on groundwater levels that were greater than 30-ft at a single point in time. This is a technically incorrect approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30-feet or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unprotected in the GSP.

TNC recommendation: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in Attachment D which provides best practices for using the NC dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). The GSP only focused on a subset of water use sectors, including urban and agricultural users of groundwater. This is problematic because key environmental uses of groundwater are not being accounted for as water supply decisions are made using this budget nor will they likely be considered in project and management actions.

---

[1] *Available at:* https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

TNC recommendation: As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Potential GDEs are located along surface water bodies where no further shallow groundwater monitoring is proposed, leaving recognized data gaps unfilled. Potential ISWs have been dismissed in the GSP, without proposed recommendations to improve ISW identification, mapping, and estimates of depletions. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential for impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Attachment A

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Central Kings Area Groundwater Sustainability Plan
Comments based on Draft and Final GSPs

The Central Kings Groundwater Sustainability Plan (CKGSP) adopted December 11, 2019 was reviewed by TNC. **The Public draft GSP comments and responses, provided as Appendix 2A of the GSP, were actually the North Kings GSA Comments and Responses. This error made it more difficult to assess whether our comments were addressed in the final GSP**. We compared the Public Draft GSP to the Final GSP to determine if TNC's comments on the Draft GSP were addressed in the Final GSP. This attachment lists our original comments on the complete public draft GSP as submitted to the GSA during the public comment period, and states whether or not they were addressed in the final GSP [as green text within brackets]. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 2.5.1 Description of Beneficial Uses and Users (p. 2-31)]

- *[Our comment was not addressed.]* The discussion of beneficial uses and users of groundwater focused on agricultural users, domestic well users, and City of Selma users, but environmental groups were not listed. **Please discuss how environmental groups were engaged during the GSP development process.**
- *[Our comment was not addressed.]* **Please identify whether or not the following beneficial uses and users of groundwater in the Subbasin are present: Protected Lands, including refuges, conservation areas, and recreational areas; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
- *[Our comment was not addressed.]* The types and locations of environmental uses, species and habitats supported, instream flow requirements, and other designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. **To identify environmental users, please refer to the following:**
    - The NC Dataset (https://gis.water.ca.gov/app/NCDatasetViewer/) which identifies the potential presence of groundwater dependent ecosystems in this basin.
    - The list of freshwater species located in the Kings Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.
    - CDFW's California Natural Diversity Database (CNDDB) - https://www.wildlife.ca.gov/Data/CNDDB
    - USFWS's IPAC report for the Central Kings GSA (CKGSA) area - https://ecos.fws.gov/ipac/

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8).

[Section 2.2.1 Monitoring and Management Programs (p. 2-10 to 2-15)]

- *[Our comment was not addressed.]* [Groundwater Level Monitoring (p. 2-10)] Consolidated Irrigation District (CID) has maintained a network of about 80 wells since 2001. The groundwater levels in these wells are currently measured two times per year. The Kings River Conservation District (KRCD) began studying groundwater level trends in 1987 and prepared annual groundwater reports between 2003 and 2014 that included regional groundwater contour maps. **Please describe how existing groundwater monitoring programs are protective of GDEs or propose additional monitoring that specifically targets GDEs.**
- *[Our comment was not addressed.]* [Groundwater Extraction Monitoring (p. 2-15)] The CID does not own or operate any municipal wells. Most private wells are not metered, so the volume extracted is not known. This omission means that the groundwater used must be estimated using factors such as water use per capita and crop water demand per acre, which contributes to the uncertainty of the water budget. **Please describe how this data gap will be filled in the future.**
- *[Our comment was not addressed.]* [Surface Water Monitoring (p. 2-15)] This section states that the Kings River is monitored by "numerous agencies" (p. 2-15) but lists only the Kings River Water Association. The Kings River Fisheries Management Program is described in Section 2.2.2 Impacts to Operational Flexibility. The Kings River program includes maintenance of a 10 percent minimum capacity in the Pine Flats Reservoir for improved temperature control and year-round fish releases below the reservoir. There is no mention of ISWs or GDEs or how they are monitored. **Please explain the relationship of existing stream flow monitoring to the protection of ISWs and GDEs, and if there are instream flow criteria for the ISWs.**

[Section 2.3 Relation to General Plans (p. 2-19 to 2-25)]

- *[Our comment was not addressed.]* The Fresno, Kings and Tulare County General Plan were adopted prior to the development of the CKGSA. This section should be modified to include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**
- *[Our comment was not addressed.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin, and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**
- *[Our comment was not addressed.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin.

[2] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.

[Section 2.3.4 Permitting of New Wells (p. 2-24)]

- *[Our comment was not addressed.]* Well permitting is handled currently by County Health Departments. The GSP states that CID will work with counties to review new well applications. **Please include a discussion of how future well permitting will be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**
- *[Our comment was not addressed.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF vs. SWRCB and Siskiyou County, No. C083239). **Compliance of well permitting programs with this requirement should be stated in the GSP.**

[Section 2.4.4 Well Abandonment/Well Destruction Program (p. 2-28)]

- *[Our comment was not addressed.]* The county of Fresno has the authority to require permits for well abandonment/well destruction, but due to staffing and funding limitations the GSP notes that enforcement of this requirement is limited. **Please describe what actions will be taken by CKGSA to make sure that wells are properly abandoned.**

<u>Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)</u>

[Section 3 Basin Setting (p. 3-1 to 3-42)]

- *[This comment was addressed. Thank for you fixing the formatting of these figures.]* The following figures in Section 3 do not show up correctly in the GSP and cause the pdf application to crash: Figures 3-9, 3-19, 3-24, and 3-25. **Please correct these figures in subsequent versions of the GSP.**

[Section 3.1.7 Cross-Sections (p. 3-14)]

- *[Our comment was not addressed.]* The basin-wide cross sections provided in Figures 3-11 through 3-16 (pp. 3-18 to 3-23) are regional, and do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. The cross-sections have been taken from a 1969 source and, as reproduced in the GSP, are very difficult to read and understand. **Please reproduce the regional cross-sections so that they can be understood by the reader and update them to illustrate data obtained from more recent well installations. Include an example near-surface cross sections that depicts the conceptual understanding of shallow groundwater and river interactions at different locations, as well as any potential GDEs and ISWs**.

[Section 3.1.8.2 Aquifer Characteristics and Properties (p. 3-28)]

- *[Our comment was not addressed.]* In the Central Kings Subbasin, the base of the usable aquifer corresponds with the base of freshwater, generally defined as groundwater with total dissolved solids (TDS) of 2,000 milligrams per liter (mg/l), consistent with other GSAs in the Kings subbasin. In the far eastern part of the Central Kings subbasin, the base of the aquifer is defined by the top of the basement complex. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.

[Section 3.1.12 Recharge and Discharge Areas (p. 3-38 to 3-42]

- *[Our comment was not addressed.]* The GSP states that there are natural recharge areas, stormwater basins and constructed recharge basins. **Please include a description of these areas and note whether any features are present that attract wildlife. Please indicate whether the recharge basins are or could be operated as multiple-benefit projects that provide habitat suitable for migrating birds or other species, and could be included in an HCP or NCCP.**
- *[Our comment was not addressed.]* Wetlands were mapped along the Kings River, as identified from US Forest Service's National Wetland Inventory, according to the GSP. **Please discuss in the GSP that these wetlands are considered potential GDEs and refer to Figure 3-63. Also, if the Wetland Inventory was in fact the US Fish and Wildlife Service (USFWS) National Wetlands Inventory (NWI), then correct the text and reevaluate the data. The NWI does not always include or segregate separate existing wetlands that are on the periphery of other features. Please describe the wetland types in more detail. If they are truly vernal pools confined by a clay layer then they are not GDEs, but they must meet the criteria of a vernal pool as described by the California Rapid Assessment Methodology or the United States Army Corps of Engineers to qualify.**

<u>Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)</u>

[Section 3.2.7 Surface Water and Groundwater Interconnection (pp. 3-89 to 3-91)]

- *[Our comment was not addressed.]* ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface Digital Elevation Model (DEM) that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. **Please provide or refer to depth to groundwater contour maps in this section. See Attachment D for best practices for completing**

this step. Specifically, ensure that the first step is contouring groundwater elevations, and the subtracting this layer from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found. Contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make.

- *[Our comment was not addressed.]* In the Kings River between Highway 180 and Sanger, shallow wells were installed at proposed gravel processing facilities and wastewater facilities by KDSA (KDSA 2017). The GSP states that the "KDSA further indicates that along the reach of the Kings River upstream of the Reedley narrows, the groundwater is indicated to be in direct hydraulic communication with streamflow in the Kings River" (p. 3-91). The groundwater in this area is shallow based on DWR measurements. This finding needs to be illustrated using cross-sections with measured channel bed elevations and depths to groundwater. **Please provide a cross-section at this location to show the relationship between the depth to groundwater and the bed of the river channel. If channel bed elevations are not known, please identify as a data gap and further discuss in the Monitoring section of the GSP.**

<u>Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)</u>

[Section 3.2.8 Groundwater Dependent Ecosystems (p. 3-91)]

- *[Our comment was not addressed.]* The NC dataset is a starting point for GSAs to identify GDEs in their basin/subbasin. The NC dataset has 991 acres of potential GDEs mapped within the CKGSA area, representing a significant amount of GDEs to be considered. Note that this is a starting point, thus not all potential GDEs are mapped and not all ecosystems mapped are GDEs. **Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled by the monitoring network**. Specifically, please note:
  - *[Our comment was not addressed.]* The text refers to Spring of 2017 depth to groundwater contours, however these contours are not shown. Figure 3-53 shows depth to groundwater contours for Spring 2015, however this figure is not referred to in this section. **Please note the following best practices for developing depth to groundwater contours**:
    - Only wells monitoring the upper unconfined aquifer are being used to verify whether polygons in the NC dataset are supported by groundwater;
    - The wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons reflect local conditions relevant to ecosystems;

        - The wells used for interpolating depth to groundwater are screened within the surficial unconfined aquifer and capable of measuring the true water table; and
        - Depth to groundwater is contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from measurements at wells assume that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to create the contour map.
    - *[Our comment was not addressed.]* It is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2017) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Ensure that groundwater condition data prior to the SGMA benchmark date of January 1, 2015 is included in the analysis. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network**.
    - *[Our comment was not addressed.]* **Please provide rationale for the 30-foot criteria cited in the text.** The text states (p. 3-91): "Recognizing that much of the Kings Subbasin has a depth to groundwater greater than the deepest vegetative GDE rooting depth of thirty feet, many of the GDEs identified in the NC Dataset Viewer were mischaracterized." In TNC's GDE Guidance, the depth criteria of 30 feet is presented as a criterion for *inclusion*, not a standalone criterion for *exclusion*. In other words, if groundwater is within 30 feet of the ground surface, then a GDE can be identified. If it is not, then further analysis must be conducted (see Appendix III of the GDE Guidance, Worksheet 1, for other indicators of GDEs). **Please indicate what vegetation is present in the possible GDEs.** The actual rooting depth of vegetation growing in the area should be considered, and this will vary by species dominance and habitats present. For example, some phreatophytes can root to 120-feet deep in more arid and drought stressed environments. Furthermore, rooting depths are likely to spatially vary based on the local

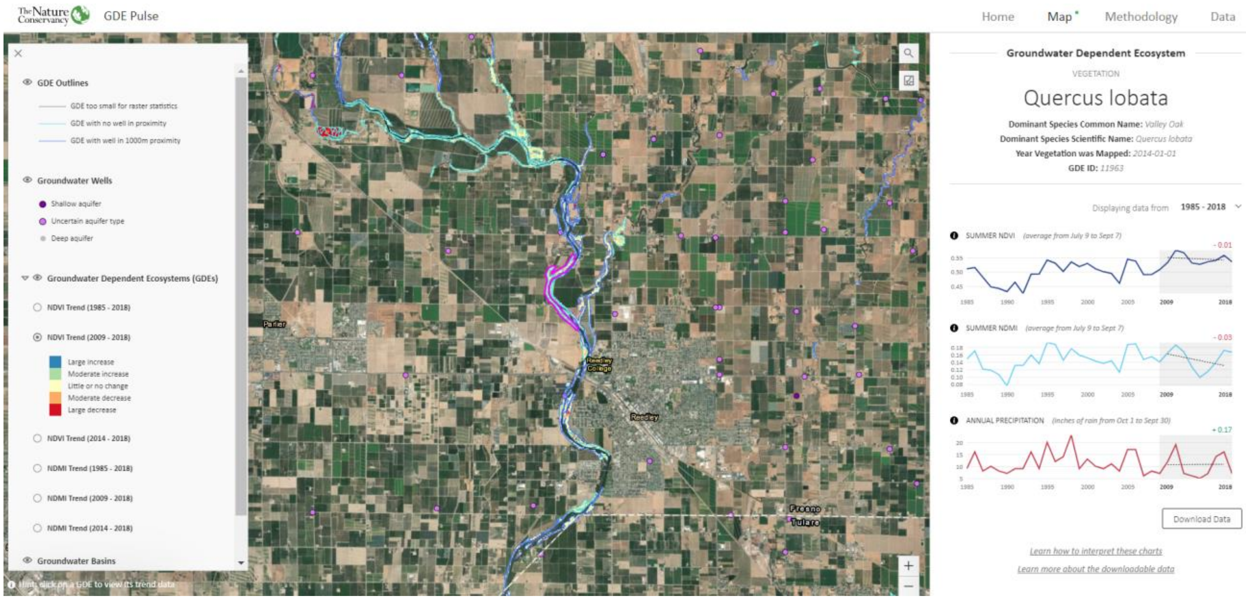
hydrologic conditions available to the plant. Maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not prefer to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths.

  - *[Our comment was not addressed.]* The text states: "The Kings Subbasin also categorized GDEs within 100 feet of the Kings River and the San Joaquin River as "Possible GDEs." **Please clarify how the 100-foot buffer was used to include or exclude GDEs in the CKGSA area, and how this is supported by groundwater level and plant physiological data. If there is a potential GDE near the river, we suggest the entire GDE is included, rather than using an arbitrary 100-foot cutoff.**
  - *[Our comment was not addressed.]* The text states (p. 3-91): "Spring 2017 depth to groundwater contours and NC Dataset viewer GDEs were overlaid to identify GDEs in areas with depth to groundwater greater than 30 feet. GDEs meeting this criterion were categorized as 'Rejected GDEs' and depicted in purple in Figure 3-62 and 3-63." However, Figure 3-62 shows rejected GDEs in *light green and pink*. Figure 3-63 shows *wetlands* in purple (not rejected GDEs). **Please correct the callouts and description of these figures. The basin's GDE shapefile, which is submitted via the SGMA Portal, should include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed). In addition, in the text please cite the acreage of GDEs retained and removed.**

Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)

[Section 3.2.8 Groundwater Dependent Ecosystems (p. 3-91)]

- *[Our comment was not addressed.]* **Please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present**. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the CKGSA area:



- *[Our comment was not addressed.]* **Please provide an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes the vegetation types or habitat types and rank the GDEs as having a high, moderate or low value; and what characterizes the rank.**
- *[Our comment was not addressed.]* **Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat, were found in or near any of the GDEs, since some organisms rely on uplands and wetlands during different stages of their lifecycle**. Resources for this include the list of freshwater species located in the Kings Subbasin that can be found in Attachment C of this letter, the Critical Species Lookbook, and CDFW's CNDDB database.
- *[Our comment was not addressed.]* **For each identifiable GDE unit with supporting hydrological datasets please include the following:**
    - Plot and provide hydrological datasets for each GDE.
    - Define the baseline period in the hydrologic data.
    - Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater.
    - Explore cause-and-effect relationships between groundwater changes and GDEs.
- *[Our comment was not addressed.]* **For each identifiable GDE unit without supporting hydrological datasets please describe data gaps and/or insufficiencies.**
- *[Our comment was not addressed.]* **Compile and synthesize biological data for each GDE unit by including:**
    - Plots of biological datasets for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.
    - Describe data gaps/insufficiencies.

- *[Our comment was not addressed.]* **Description of potential effects on GDEs, land uses, and property interests, including:**
  - Cause-and-effect relationships between GDE and groundwater conditions.
  - Impacts to GDEs that are considered to be "significant and unreasonable".
  - Report known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities.
  - Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).
  - Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 3.3.9 Historical Water Budget (p. 3-110)]

- *[Our comment was not addressed.]* **Please clarify whether a term is included for native or riparian vegetation evapotranspiration and for wetlands in the CKGSA area historical, current, and future water budgets.**

[Section 3.3.11 Projected Water Budget (p. 3-117)]

- *[Our comment was not addressed.]* Given the uncertainty associated with Kings River water supply into the future, the assumption was made that the historical water delivery from the Kings River would be maintained. This assumption is highly uncertain and is not conservative. The diversion of Kings River flows may require additional provision for storage in the non-irrigation or low-irrigation season. **Please add discussion of the potential impacts to the flow in the Kings River and to groundwater conditions on GDEs, aquatic ecosystems and instream flow requirements due to climate change.**

<u>Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)</u>

[Section 4.1 Sustainability Goal (p. 4-4)] The Sustainability Goal does not consider GDEs or ISWs.

- *[Our comment was not addressed.]* **Since GDEs are likely present in the CKGSA area (see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included.**
- *[Our comment was not addressed.]* The Plan states that there are ISWs along the Kings River. Information that supports the potential ISWs along this river include Figure 3-62 that identifies potential GDEs, and the depth to water data for Spring 1997 and Spring 2012 presented at the end of Section 3 (Appendix 3C, Technical Memorandum 4). **Please identify and describe all ISWs and include them in the GSP.**

- *[Our comment was not addressed.]* GDEs are dependent, in part, on suitable water quality; however, the Plan only considers water quality for irrigation and domestic use. **TNC recommends including ISWs and their potential GDEs in the sustainability goal and criteria. Since GDEs may be affected by water quality, they should be included in the Sustainability Goal.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Sections 4.2.3 Measurable Objectives for Groundwater Levels (p. 4-46)]

- *[Our comment was not addressed.]* This Measurable Objective does not consider GDEs. GDEs are often adjacent to streams or associated with riparian corridors where ISWs exist, even if only seasonally or discontinuously along a longitudinal or lateral profile. **Please include GDEs (see comments under Checklist Items 8-10) in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.4 Measurable Objectives for Water Quality (p. 4-63)]

- *[Our comment was not addressed.]* This Measurable Objective does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.7.2 Measurable Objectives for Interconnected Surface Water (p. 4-71)]

- *[Our comment was not addressed.]* The text states (p. 4-71): "Undesirable results to surface water related to groundwater pumping the Kings Basin are not likely to occur and criteria, including measurable objectives has therefore not been set for the Kings Basin under regulation §354.26(d)." Because ISWs do occur in the CKGSA area (p. 3-91), then Sustainable Management Criteria including Measurable Objectives should be established. The GSP has not shown evidence that undesirable results related to this sustainability indicator are not likely to occur. **Please further discuss ISWs in this section and set measurable objectives and interim milestones to help achieve the sustainability goal as it pertains to the environment.**

Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28)

[Sections 4.2.2 Minimum Thresholds for Groundwater Levels (p. 4-26)]

- *[Our comment was not addressed.]* This Minimum Threshold does not consider GDEs. **Please include GDEs in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.3 Minimum Thresholds for Groundwater Quality (p. 4-61)]

- *[Our comment was not addressed.]* This Minimum Threshold does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 4.2.1 Undesirable Results for Groundwater Levels (p. 4-5)]

- *[Our comment was not addressed.]* This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses and users that could be adversely affected by chronic groundwater level decline. **Please add potential adverse impacts to GDEs and native freshwater species to the discussion of potential undesirable results presented in this section.**
- *[Our comment was not addressed.]* The GDE Pulse web application developed by TNC provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within and near the GSA. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture along the Kings River. An example screen shot from the GDE Pulse tool is presented under Checklist Items 11-15 above.

[Section 4.5.2 Undesirable Results for Groundwater Quality (p. 4-59)]

- *[Our comment was not addressed.]* This section describes undesirable results in terms of meeting drinking water standards. The following is a link to a paper by Smith, Knight and Fendorf (2018) titled "Overpumping leads to California groundwater arsenic threat": (https://www.nature.com/articles/s41467-018-04475-3). **The section should be modified to state that overpumping and dewatering of aquitards has been identified as a potential source of elevated arsenic concentrations above drinking water standards in San Joaquin Valley aquifers. In addition, any potential undesirable results from degradation of water quality that may impact GDEs and freshwater species in the area should be discussed in this section.**

[Section 4.7.1 Undesirable Results for Interconnected Surface Water (p. 4-71)]

- *[Our comment was not addressed.]* The text states (p. 4-71): "Due to existing river management programs and/or the lack of continuous interconnected surface water within the Kings Basin, undesirable results to surface water related to groundwater pumping are not likely to occur." GDEs are often adjacent to streams or associated with riparian corridors where ISWs exist, even if only seasonally or are discontinuous along a longitudinal profile. ISWs that are not continuously connected spatially and/or temporally are still ISWs and should not be excluded from this GSP. **Even when ISWs are not continuously connected, they should be included in the Measurable Objectives. Please include GDEs and ISWs in this section and**

whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.

- *[Our comment was not addressed.]* The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial uses and users of surface water that could be affected by groundwater withdrawals, including environmental users. **Please state in this section whether there are any instream flow requirements and critical habitat designations and set measurable objectives and interim milestones to help achieve the sustainability goal as it pertains to the environment.**

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

[Section 5.2 Groundwater Level Monitoring (pp. 5-3 to 5-12)]

- *[Our comment was not addressed.]* **Please address how the need to link and correlate groundwater level declines to biological responses and significant and adverse impacts to GDEs and ISWs will be addressed by the monitoring network.**
- *[Our comment was not addressed.]* The proposed wells to be used for monitoring groundwater levels are shown in Figure 5-1 (p. 5-6). The figure shows which monitoring wells have well construction information. The text mentions areas to be monitored include the unconfined aquifer and the confined aquifer below the Corcoran Clay in the western part of the CKGSA area. No distinction is shown on Figure 5-1 for wells screened in the unconfined or confined aquifer. **Please distinguish on this figure which wells will be used to monitor the unconfined and confined aquifers. To accurately characterize GDEs, please clarify how the unconfined aquifer will be monitored and how many wells will be used.**

[Section 5.7 Depletion of Interconnected Surface Water Monitoring (pp. 5-30 to 5-35)]

- *[Our comment was not addressed.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *and related surface conditions* (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of complicated factors, and this relationship is not characterized or discussed. As such, it is not possible to determine whether the proposed monitoring is sufficiently protective to ensure significant and unreasonable impacts to GDEs and ISWs will be prevented. **To clarify if GDEs are present, consider adding monitoring of potential GDEs at any locations where ISWs are present regardless of their seasonal or discontinuous nature.**
- *[Our comment was not addressed.]* The text states (p. 5-35): "The river invert adjacent to Wells 31 and 41 will be surveyed to determine the invert and compare to the levels depicted in the hydrographs." This is the only data gap identified with respect to ISWs. **Please further reconcile data gaps in monitoring for ISWs**

with specific recommendations (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features to improve ISW mapping and inform an adequate analysis.

Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Section 6.1 Introduction (pp. 6-3 to 6-5)]

- *[Our comment was not addressed.]* The CKGSA area includes GDEs and ISWs (see our comments under Checklist Items 8-10 and 16-20 above) that are beneficial uses and users of groundwater and may include potentially sensitive resources and protected lands. Environmental resource protection needs should be considered in establishing project priorities. In addition, consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**

[Section 6.2 Projects (pp. 6-6 to 6-11)]

- *[Our comment was not addressed.]* This section identifies multiple recharge projects; however, the descriptions of Measurable Objectives for these projects only identifies benefits to water level and storage. Because maintenance or recovery of groundwater levels, or construction of recharge facilities, may have potential environmental benefits in many cases it would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.
    - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
    - If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting ISWs.**
    - Recharge ponds, reservoirs and facilities for managed stormwater recharge projects can be designed as multi-benefit projects that include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such facilities have been incorporated into local Habitat Conservation Plans (HCPs) and Natural Community Conservation Plans (NCCPs), more fully recognizing the value of the habitat that they provide and the species they support. **For projects that construct recharge ponds, consider identifying if there is habitat value incorporated into the design and how the recharge ponds will be managed to benefit environmental users. Grant and funding opportunities for SGMA-related work may apply to multi-benefit projects that can address water quantity as well as provide environmental benefits. Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**

- For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

[Section 6.3 Management Actions (p. 6-11)]

- *[Our comment was not addressed.]* This section states that CKGSA does not plan to use Management Actions to meet sustainability goals (p. 6-11). **Please consider adding Management Actions which include education and outreach for protection of GDEs and ISWs as well as specific management of these ecosystems and the species they provide for.**

Attachment C

Freshwater Species Located in the Kings Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Kings Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[4] as well as on TNC's science website[5].

Scientific Name	**Common Name**	**Legally Protected Species**		
		Federal	**State**	**Other**
Birds				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	BCC	SCC	BSSC - First priority
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anas strepera	Gadwall			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron			
Aythya affinis	Lesser Scaup			
Aythya americana	Redhead		SCC	BSSC - Third priority
Aythya collaris	Ring-necked Duck			
Aythya marila	Greater Scaup			
Aythya valisineria	Canvasback		SCC

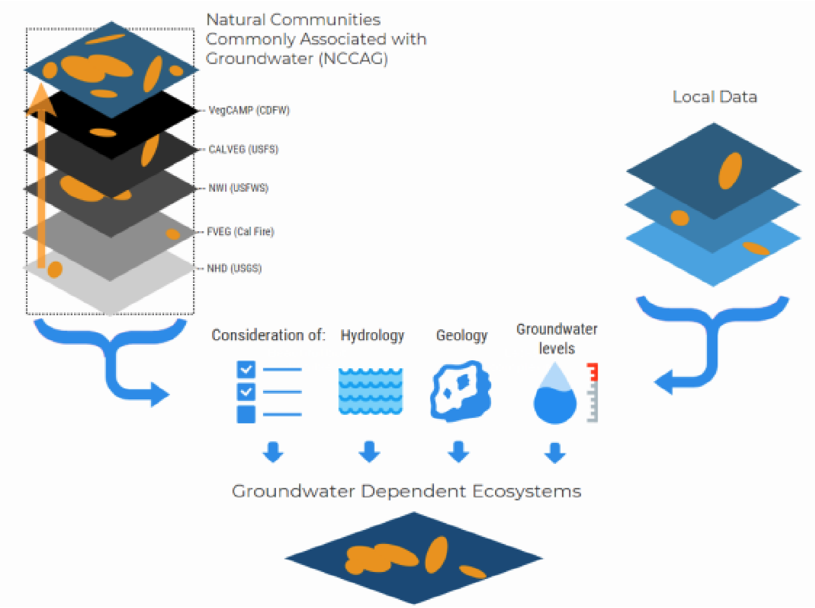
IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48

[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

[8] *For more details on the mapping methods, refer to: Klausmeyer, K., J. Howard, T. Keeler-Wolf, K. Davis-Fadtke, R. Hull, A. Lyons. 2018. Mapping Indicators of Groundwater Dependent Ecosystems in California: Methods Report. San Francisco, California. Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/iGDE_data_paper_20180423.pdf*

[9] "Groundwater Dependent Ecosystems under the Sustainable Groundwater Management Act: Guidance for Preparing Groundwater Sustainability Plans" is available at: https://groundwaterresourcehub.org/gde-tools/gsp-guidance-document/

[10] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

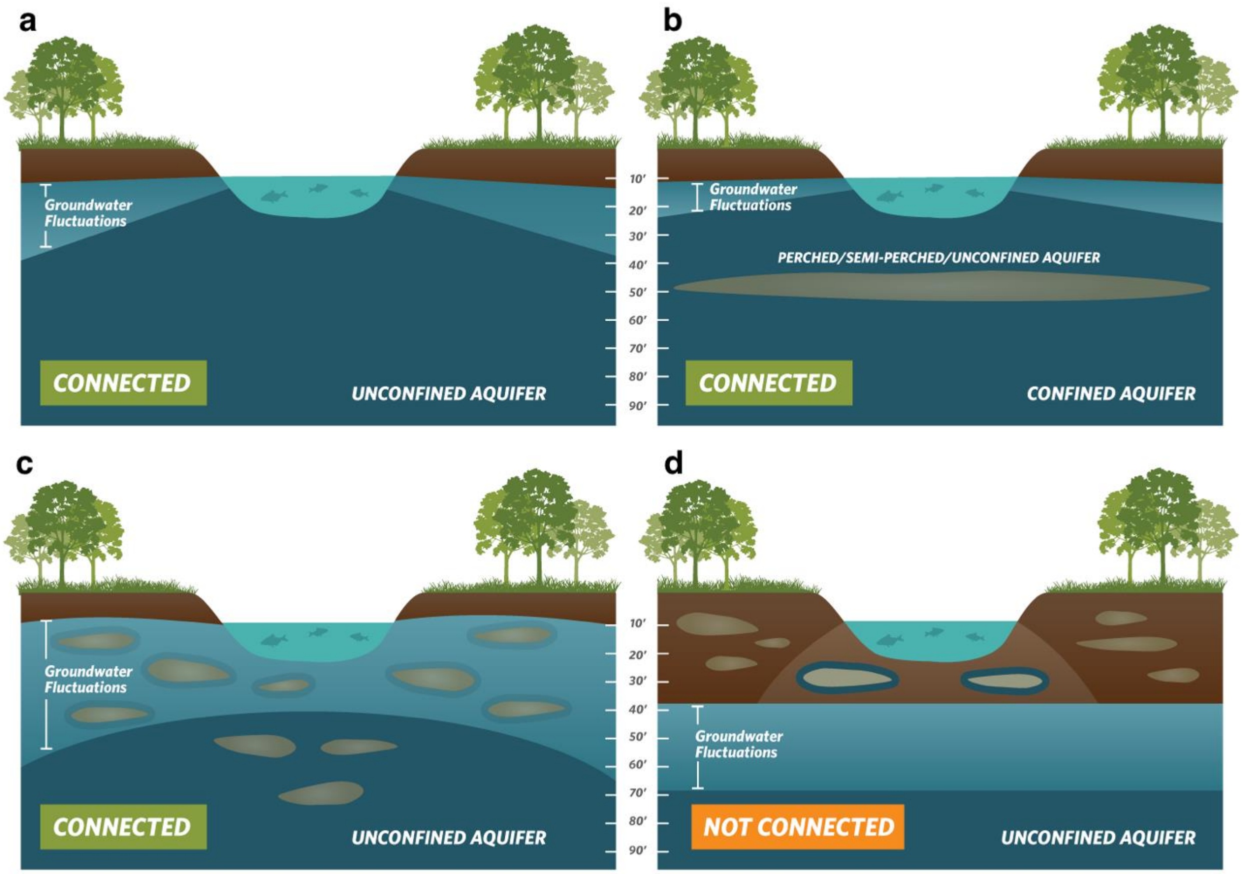

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

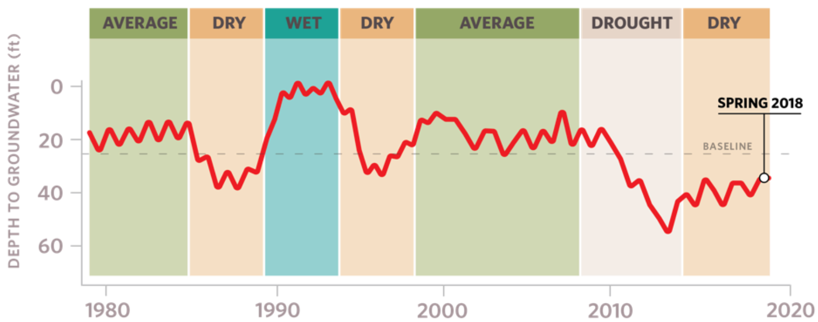

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

---

[11] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

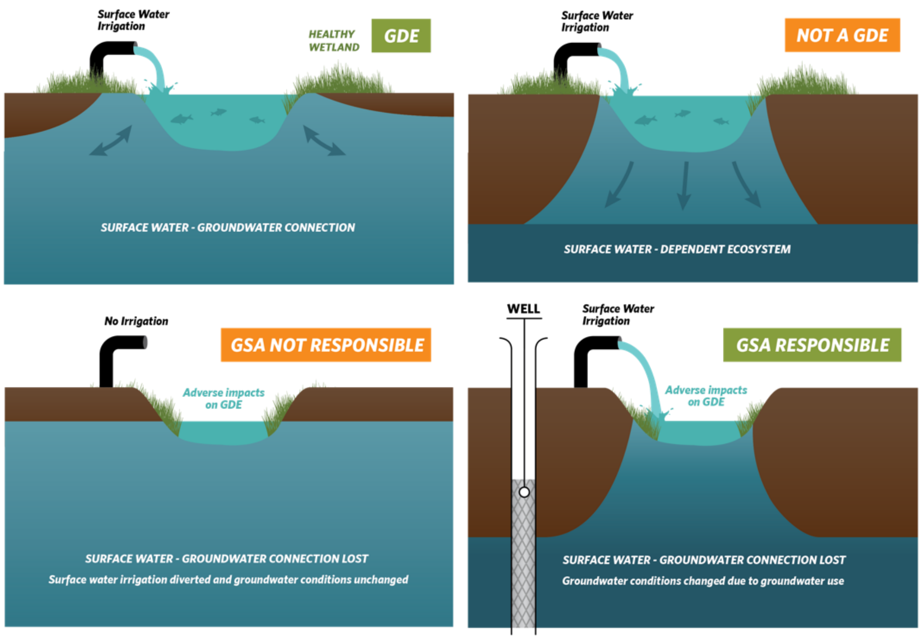

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

---

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

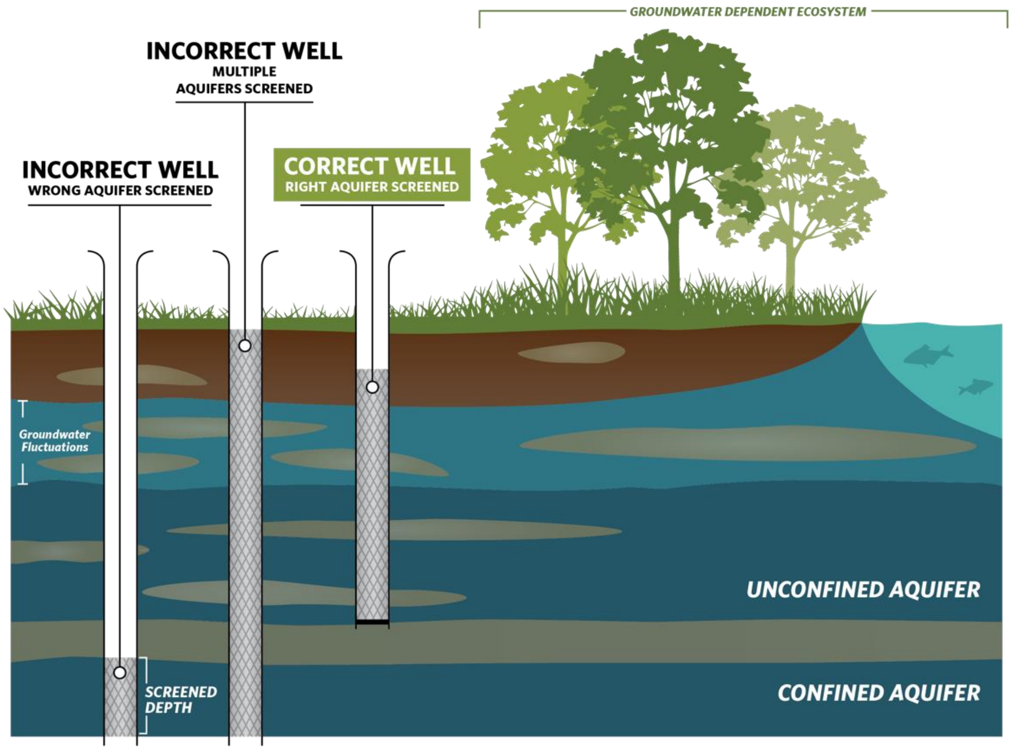

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

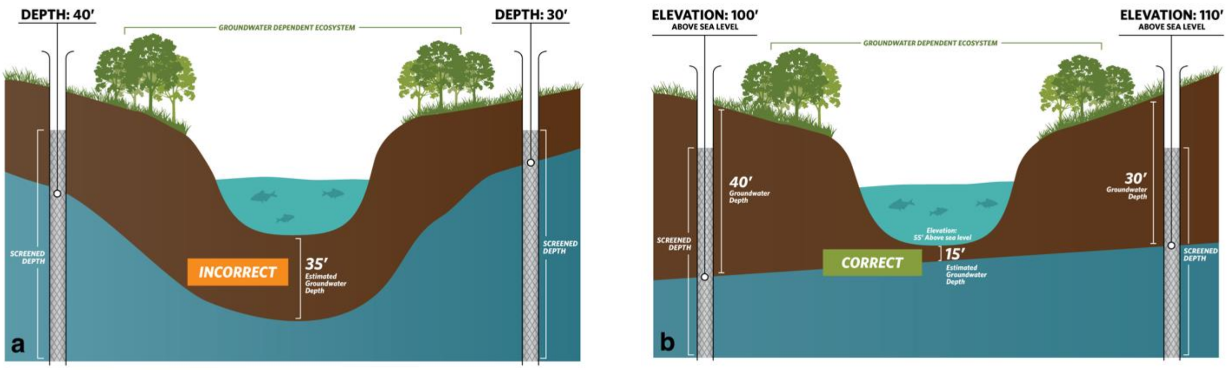

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

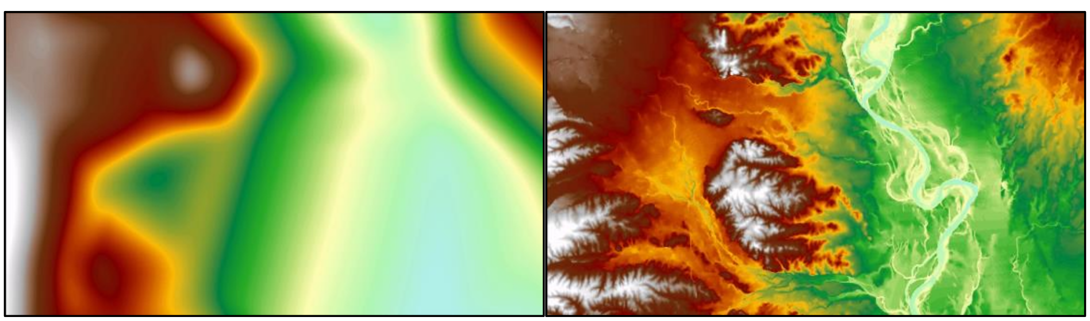

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[16] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

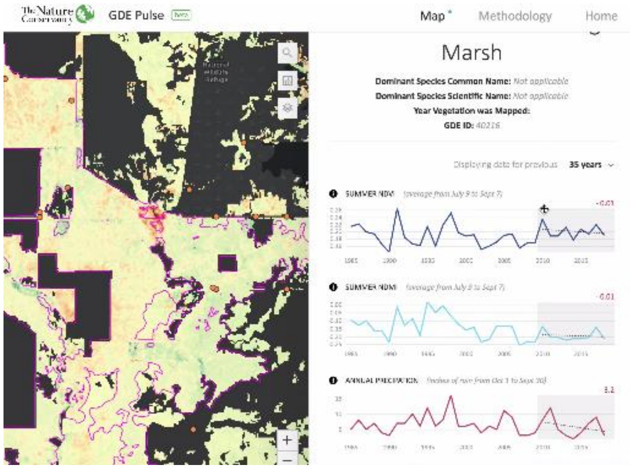
The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Attachment E

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as “surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted” (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates “feet above or below mean sea level” based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2011-2018)

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Chowchilla Subbasin Groundwater Sustainability Plan (GSP), Chowchilla Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Chowchilla Subbasin Groundwater Sustainability Agency's (GSA's) Chowchilla Subbasin Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be incomplete in addressing environmental beneficial uses and users.

While the GSP addressed environmental beneficial users in some respects, our review finds that portions of the GSP should be remedied before being approved. Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of potential ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section.

We appreciate that the GSA incorporated a portion of our feedback (21 of 41 comments were addressed), however, we disagree with the components where our feedback was ignored or dismissed. This suggests a limited degree of engagement of environmental beneficial users and could result in a definition of sustainability that is biased towards a limited set of users in the basin. In our experience, the GSP did not "adequately respond(d) to comments that raise credible technical or policy issues with the Plan," (23 CCR §355.4(b)(10).

TNC recommendation: We recommend that DWR require the GSA to prioritize stakeholder engagement, resulting in stakeholder input being incorporated into the plan. Improvements can be achieved through enhancements to the stakeholder engagement plan, partnerships with NGOs and community members, more representative governance and funding decisions.

Interconnected Surface Waters (ISWs) – The GSP incorrectly ignored potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were incorrectly removed based on the characterization that losing streams are necessarily disconnected. This justification for removal was not substantiated with further data or analysis. The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. Therefore, potential ISWs are not being managed in the GSP. Specifically, our analysis of groundwater levels from 2011 to 2018 indicate portions of the reach of the San Joaquin River that flows through the GSP area are connected (see Attachment G). Therefore, potential ISWs may have been improperly omitted.

Map and Assessment of potential ISWs:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the Chowchilla Subbasin GSP, 2.1 are losing and the rest are uncertain or likely disconnected. Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on surface water-groundwater interconnectivity and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 986 acres of potential GDEs occur in the GSA boundary. TNC developed the Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

We were pleased to see that the GSP took steps to identify and map GDEs following TNC guidance. In particular, the San Joaquin River Riparian GDE unit was analyzed for hydrologic and ecological conditions, including an inventory of species and ecological value and a discussion of field studies and reconnaissance. TNC's GDE Pulse was used to examine NDVI and NDMI trend data for the GDE polygons within the GDE unit.

However, we found that some GDEs were improperly disregarded. We recommend that the GSP remedy the omissions by following our recommendations in Attachment B. The GSP should also revisit all components of the plan where GDEs, as a beneficial user, must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives. Our review found that NC Dataset polygons were improperly removed from the GDE map based on the following:

- GDEs were rejected on the basis that groundwater depths were greater than 30-feet. The GSA used groundwater depths from two dates (2014 and 2016), however both represent a drought period. This is a technically incorrect approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30-feet or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unprotected in the GSP.
- GDEs located next to net-losing streams were rejected. This selected removal criteria does not necessarily prove that the plants and animals do not access groundwater, as near losing reaches groundwater gradients are close enough to the surface to support ecological communities such as riparian vegetation. Analyzing groundwater levels is a more scientifically robust approach to validate the NC dataset, since GDEs are defined as 'ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface' [23 CCR § 350(m)].

<u>TNC recommendation</u>: We request that the GSA use groundwater levels that represent interannual and inter-seasonal variability that are fully characteristic of California's climate. We recommend the use of additional information provided in our guidance document (Attachment D) to identify and consider GDEs throughout the GSP.

[1] *Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf*

Water Budget – We would like to commend the GSP for including the groundwater demands of native vegetation and managed wetlands in the historical, current and projected water budgets.

Sustainable Management Criteria – The GSP took steps towards including environmental beneficial users of groundwater and interconnected surface water, however, the Sustainable Management Criteria should be improved to describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). The GSP incorrectly states that the depletions to interconnected surface water Sustainable Management Criteria are not applicable to the subbasin, however ISWs were incorrectly removed based on characterization that losing streams are necessarily disconnected. Thus, critical habitat for threatened Central Valley steelhead and Central Valley spring-run Chinook salmon, which are beneficial users of surface water, may be adversely impacted, resulting in undesirable results.

<u>TNC recommendation</u>: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters, including steelhead and salmon. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – While the monitoring network ensures partial coverage of sustainability indicators, the network should be improved to ensure adequate coverage of sustainability indicators, characterize the spatial and temporal exchanges between surface water and groundwater, and calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions required under SGMA (23 CCR §354.34(c)(6) and (f)(3). The Monitoring Network section of the GSP currently does not address future needs for ISW monitoring, leaving data gaps on critical habitat for threatened species unprotected.

<u>TNC recommendation</u>: TNC recommends that the GSP (1) reconcile data gaps for the investigation and monitoring program including stream gauges, screened intervals and frequency of monitoring to verify the extent of ISWs; and (2) discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions as required by SGMA.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto

Associate Director, California Water Program
The Nature Conservancy

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Chowchilla Subbasin Groundwater Sustainability Plan

A complete draft of the Chowchilla Subbasin Groundwater Sustainability Plan (GSP), adopted in January 2020, was reviewed by TNC. Responses to comments are provided in Appendix 2.C.e of the Final GSP. The response to comments is also provided in Attachment F of this letter. We reviewed the responses to comments and the text of the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the Chowchilla Subbasin GSA during the public comment period, and states whether or not they were addressed in the Final GSP *[as green text within brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 2.1.5.2 Description of Beneficial Uses and Users (p. 2-21)]

- *[The Environmental and Ecosystem category of interest in Table 2-4 has been expanded with the names of specific groups. Thank you for acknowledging the importance of recognizing environmental stakeholders.]* The GSP authors have listed environmental agencies and environmental groups as one of the beneficial users of groundwater in the Subbasin in Table 2-4 (p. 2-20 to 2-21). The following footnote was added to the table: "The groups and communities referenced are examples identified during initial assessment. GSA Interested Parties lists shall maintain current and more exhaustive lists of stakeholders fitting into these groups." Environmental groups should be expanded in a manner similar to the environmental justice groups in the Human Right to Water category. **Please expand the stakeholder list associated with the Environmental and Ecosystem Uses category in Table 2-4 to include the appropriate agencies and list of environmental groups**.
- *[The GSA's response states: "See Multiple Comment Subject Area Response." However, this response did not address our comment, nor were any changes made to the GSP text.]* The types and locations of environmental uses, species and habitats supported, instream flow requirements, and other designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. **To identify environmental users, please refer to the following**:
    - The NC Dataset (https://gis.water.ca.gov/app/NCDatasetViewer/) which identifies the potential presence of groundwater dependent ecosystems in this basin
    - The list of freshwater species located in the Chowchilla Subbasin in **Attachment C** of this letter. Please take particular note of the species with protected status.

- CDFW's California Natural Diversity Database (CNDDB) - https://www.wildlife.ca.gov/Data/CNDDB
- USFWS's IPAC report for the Chowchilla Area - https://ecos.fws.gov/ipac/
- Lands that are protected as open space preserves, habitat reserves, wildlife refuges, etc. or other lands protected in perpetuity and supported by groundwater or interconnected surface waters should be identified and acknowledged.

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8

[Section 2.1.2.2 Surface Water Monitoring and Management Programs (p. 2-8 to 2-10)]

- *[The following text was added explanation to Section 2.1.2.2: "These monitoring stations are important for monitoring surface water available to interconnected surface water (ISW) habitats and groundwater dependent ecosystems (GDEs)." Thank you for acknowledging the importance of monitoring for ISWs and GDEs in this section.]* This section describes the types of monitoring performed by federal, state and local agencies of surface water inflows, outflows, and irrigation releases. The monitoring stations for flows and water deliveries are listed in Table 2-3. Local stations for flow or irrigation releases are listed in the text (p. 2-8 to 2-9). **Please explain the relationship of existing stream flow monitoring to the protection of ISWs and GDEs.**
- *[In Section 2.1.2.2, a footnote was added to sentences referencing the SJRRP program that described this purpose and the annual calculation of instream flow requirements (p. 2-8, 2-19). Thank you for clarifying this in the GSP.]* There is no discussion of the in-stream flow requirements for the San Joaquin River or any other surface water. The San Joaquin River Restoration Program (SJRRP) requires the release of flows from Friant Dam to the confluence with the Merced River to support the life-stages of salmon and other fish species. This section should discuss or reference any instream flow requirements, especially flow needs for critical species, including the amount, time of year when the flow minimum is specified, the duration, the species for which it applies, associated permits that set forth the requirements, and the regulating agency setting forth the compliance requirements. **Please discuss the future impact of the SJRRP on the riparian areas and potential GDEs present along or adjacent to the river.**

[Section 2.1.3.1 Madera County General Plan (p. 2-12 to 2-14)]

- *[Further description was added to Section 2.1.3.1 of the GSP. Thank you for acknowledging how General Plan policies are coordinated with protection of wetlands, aquatic resources, and other GDEs and ISWs.]* The Madera County General Plan from 1995 (with updates from 2015) includes restrictions on development in "areas with sensitive environmental resources" (Policy 1.A.5) and provides "the preservation of natural vegetation, land forms, and resources as open space, with permanent protection where feasible" (Policy 5.H.1) (p. 2-12). This section should include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**

- *[Further description was added to Section 2.1.3.1 of the GSP. Thank you for stating how implementation of the GSP will be coordinated with General Plan policies.]* The Merced County General Plan adopted in December 2013 and amended in 2016 "has established policies to promote compact development of existing or well-planned new urban communities established apart from productive agricultural land, to limit growth in rural centers, and to forbid development adjacent to wetland habitat (Policies LU-1.1-5, 7, 9-10, 13)" (p. 2-13). Agricultural land uses "shall not have a detrimental effect on surface water or groundwater resources." **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**
- *[Further description added to Section 2.1.2.1 of the GSP. The PG&E San Joaquin Valley Operations & Maintenance Habitat Conservation Plan overlaps with Chowchilla Subbasin. No NCCPs overlap with the Chowchilla Subbasin (https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=68626&inline).]* These sections should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**
- *[The GSA's response states: "See the discussion of the San Joaquin River GDE Unit in section 2.2.2.6 for information on special status species. Also see the discussion of the GDE Monitoring Program in Section 3.5.2.5 and the GDE Appendix 2.B for more information on special species and management of critical habitat." Thank you for clarifying the location of these items in the GSP.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**

[Section 2.1.3.4 Permitting Process for Wells in Chowchilla Subbasin (p. 2-15 to 2-16)]

- *[Further description added to Section 2.1.3.4 of the GSP. Thank you for acknowledging the importance of coordination of well permitting with the GSP's sustainability goals.]* Madera County Environmental Health Division has an online well permitting system that includes agricultural wells, observation/monitoring wells, community water supply wells, and individual domestic water supply wells. There is a requirement for new wells to "include a flow measurement device on new wells and the resulting groundwater pumping records" (p. 2-9). Other requirements follow the State standards (DWR, 1981). **Please include a discussion of how future well permitting will be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**

---

[2] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

- *[Further description added to Section 2.1.3.4 of the GSP. Thank you for recognizing compliance of well permitting programs with this requirement.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF vs. SWRCB and Siskiyou County, No. C083239). **Compliance of well permitting programs with this requirement should be stated in the GSP.**
- *[The GSA's response states: "The potential conversion of a well designated for abandonment as a monitoring well should be handled on a case by case basis. The clear definition of Upper and Lower Aquifers that exists in the Western Management Area does not necessarily exist in the Eastern Management Area, where the Corcoran Clay becomes shallow and the Upper Aquifer is unsaturated (or only contains a thin perched aquifer) and/or the Corcoran Clay pinches out. In addition, the history of water level data at the well should also be considered." No GSP text changes were made however.]* Madera County allows wells designated for abandonment to be converted into a monitoring well. **Please clarify in the text that only wells screened in one aquifer and appropriate for monitoring will be include in the monitoring program.**

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 2.2.1.2 Lateral and Vertical Subbasin Boundaries (p. 2-26 to 2-27)]

- *[Edits were made to the text to address this comment. Thank you for properly defining the vertical subbasin boundary.]* In the Chowchilla Subbasin, the base of the usable aquifer corresponds with the base of fresh water, generally defined as groundwater with total dissolved solids (TDS) of 1,000 milligrams per liter (mg/l) as modified from Page (1973), except in the eastern part of the basin where the of basement complex is shallower. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.
- *[The GSA's response states: "The referenced cross sections do show recent groundwater levels for the Upper Aquifer, which demonstrate a clear lack of surface water-groundwater connection throughout the subbasin. The depth to shallow groundwater, including the perched/mounded shallow groundwater levels along the San Joaquin River, are further illustrated in Figures 2-70 and 2-71." Please illustrate or refer to the perched/mounded shallow groundwater levels along the San Joaquin River in a cross-section diagram.]* The cross sections in Chapter 2 (Figures 2-23 through 2-33) clearly show the base of freshwater and the top of the basement rocks. However, they do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the

reader to understand this topic. **Please include an example near-surface cross section that depicts the conceptual understanding of shallow groundwater and river interactions at different locations, as well as potential GDEs and ISWs**.

Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISWs) (23 CCR §354.16)

[Section 2.2.2.5 Groundwater-Surface Water Interaction (p. 2-41)]

- *[The GSA's response refers to the Multiple Comment Subject Area Response for ISWs. This response does not address our comment; however, text was added to the GSP on p. 2-42 that clarifies how depth to groundwater contour maps were prepared.]* The text states (p. 2-41): "A review of historical regional aquifer groundwater levels compared to stream thalweg (deepest portion of stream channel) elevations conducted for this study indicate that surface water – groundwater interactions are not a significant issue (i.e., regional groundwater levels are relatively far below creek thalweg elevations) along Chowchilla River, Ash Slough, and Berenda Slough in Chowchilla Subbasin." ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface Digital Elevation Model that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. **Please provide further evidence that that ISWs are not present along Chowchilla River, Ash Slough, and Berenda Slough, such as a cross-section or corresponding hydrographs to show the relationship between the river channel and the depth to groundwater at wells near the rivers.**
- *[The GSA's response refers to the Multiple Comment Subject Area Response for ISWs. This response does not address our comment; however, text was added to the GSP on p. 2-42 that clarifies how depth to groundwater contour maps were prepared.]* Figures 2-70 and 2-71 present depth to shallow groundwater for 2014 and 2016. There are large data gaps over the Chowchilla Subbasin, particularly for 2016 (Figure 2-71). **Please further describe how these figures were developed, specifically noting the following best practices for developing depth to groundwater contours presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and the subtracting this layer from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape**. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make.
- *[The GSA's response refers to the Multiple Comment Subject Area Response for ISWs. This response states: "While shallow groundwater levels rise and fall from wet to dry season and wet year to dry year and may become connected to surface water for shorter durations, defining an interconnected surface water – groundwater system should require that such a connection exists under a broader range of seasonal and climatic year conditions." This sentence demonstrates an*

interconnection, as defined by SGMA. Our comment was not addressed.] The regulations [23 CCR §351(o)] define interconnected surface waters (ISW) as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. The GSP states in several places that the San Joaquin River is losing in the section adjacent to the Subbasin, and uses this as evidence that ISWs do not exist. However, ISWs can be either gaining or losing. The defining feature of disconnected surface waters is that groundwater is consistently below surface water features such that an unsaturated zone always separates surface water from groundwater, not whether the reach is gaining or losing. **To improve ISW mapping, please reconcile data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features in the Monitoring Network section of the GSP.**

- *[The GSA's response refers to the Multiple Comment Subject Area Response for ISWs. This response states in part: "While shallow groundwater levels rise and fall from wet to dry season and wet year to dry year and may become connected to surface water for shorter durations, defining an interconnected surface water – groundwater system should require that such a connection exists under a broader range of seasonal and climatic year conditions." This sentence demonstrates an interconnection, as defined by SGMA. Our comment was not addressed.]* The GSP states (p. 2-40): "It is likely that seepage from the San Joaquin River is the source of water that combined with the presence of shallow clay layers that serves to maintain shallow groundwater levels at these locations." **Please provide estimates of current and historical surface water depletions for ISWs quantified and described by reach, season, and water year type.**

<u>Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)</u>

[Section 2.2.2.6 Groundwater Dependent Ecosystems (p. 2-40)]
[Appendix 2.B (Assessment of Groundwater Dependent Ecosystems)]

- *[The GSA's response states: "See Multiple Comment Subject Area Response for GDEs. A DTW cutoff of 30 feet was used as one of the primary criteria in the initial screening of potential GDEs. It was not used as a stand-alone criterion for exclusion of potential GDEs. Edits made in Section 2.2.2.6 (pg. 2-40) to further explain and clarify." The text was updated to state that GDEs located next to net-losing streams were excluded. However, this reasoning for excluding GDEs is not correct.]* The text states (p. 2-40): "A DTW cutoff of 30 feet was used in the initial screening of potential GDEs. The use of a 30-foot DTW criterion to identify potential GDEs is based on reported maximum rooting depths of California phreatophytes and is consistent with guidance provided by The Nature Conservancy (Rohde et al. 2018) for identifying potential GDEs." We have the following comments regarding this sentence and on the methodology for identifying GDEs in the Subbasin.

- *[The GSA's response states: "See Multiple Comment Subject Area Response for GDEs. Where DTW was greater than 30 feet, other criteria such as river hydrology (flow permanence and gaining vs. losing reaches) and dominant vegetation were used to determine whether potential GDEs should be considered as final GDEs. Screening of potential GDEs also included field evaluation of potential GDEs where initial uncertainty was high. Edits made in Section 2.2.2.6 (pg. 2-40) to further explain and clarify." The text was updated to state that GDEs located next to net-losing streams were excluded. However, this reasoning for excluding GDEs is not correct.] 30-ft criteria from TNC Guidance:* In TNC's GDE Guidance, the depth criterion of 30 feet is presented as a criterion for inclusion, not a standalone criterion for exclusion. In other words, if groundwater is within 30 feet of the ground surface, then a GDE can be identified. **If it is not, then further analysis must be conducted (see Appendix III of the GDE Guidance, Worksheet 1, for other indicators of GDEs).**
- *[The GSA's response states: "Comment noted. Our analysis considered all available data on vegetation rooting depth and the importance of capillary action, as well as recent published research indicating variability in rooting depth according to local topography and groundwater conditions."] 30-ft as maximum rooting depths of California phreatophytes:* Please use care when considering rooting depths of vegetation. While Valley Oak (*Quercus lobata*) have been observed to have a max rooting depth of ~24 feet (https://groundwaterresourcehub.org/gde-tools/gde-rooting-depths-database-for-gdes/), rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant. Also, max rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not like to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths. In addition, while it is likely to be true that shallow water availability is necessary to support the recruitment of saplings, hydraulic lift of groundwater to shallow depths has been observed in *Quercus* spp.
- *[The GSA's response states: "See Multiple Comment Subject Area Response for GDEs. The 2014 and 2016 DTW data were the most accurate and recent DTW data available for the Chowchilla Subbasin. While the 2016 data represent conditions after the 2015 SGMA baseline, the use of shallow groundwater data from both years was deemed appropriate because it provided a more conservative (i.e., more inclusive) indicator of potential GDEs than the use of a data from a single year. Omitting 2016 data as suggested by TNC would reduce the number and extent of potential GDEs. Edits made in Section 2.2.2.6 (pg. 2-40) to justify the use of both 2014 and 2016 data." A comparison of depth to groundwater in 2014 and 2016 (Figures 2-70 and 2-71) show that depth to groundwater has increased during this time period. Because depth to groundwater was greater in 2016, this would be a <u>less</u> inclusive condition and thus the reasoning provided in this response is not valid.] Use of depth to water maps from 2014 and 2016:*

- 2016 is after the SGMA benchmark date of January 1, 2015. **Please rely on groundwater condition data prior to the SGMA benchmark date.**
- **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network.** While depth to groundwater levels within 30 feet are generally accepted as being a proxy for confirming that polygons in the NC dataset are connected to groundwater, it is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one or two points in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Based on a study we recently submitted to Frontiers in Environmental Science Journal, we've observed riparian forests along the Cosumnes River to experience a range in groundwater levels between 1.5 and 75 feet over seasonal and interannual timescales. Seasonal fluctuations in the regional water table can support perched groundwater near an intermittent river that seasonally runs dry due to large seasonal fluctuations in the regional water table. While perched groundwater itself cannot directly be managed due to its position in the vadose zone, the water table position within the regional aquifer (via pumping rate restrictions, restricted pumping at certain depths, restricted pumping around GDEs, well density rules) and its interactions with surface water (e.g., timing and duration) can be managed to prevent adverse impacts to ecosystems due to changes in groundwater quality and quantity under SGMA.

- *[The GSA's response states: "See Multiple Comment Subject Area Response for GDEs." This response does not address our comment; however, text was added to the GSP on p. 2-42 that clarifies how depth to groundwater contour maps were prepared.]* **Please provide more details on how depth to groundwater contour maps were developed (Figures 2-70 and 2-71)**:
  - Are the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons to reflect local conditions relevant to ecosystems?
  - Are the wells used for interpolating depth to groundwater screened within the surficial unconfined aquifer and capable of measuring the true water table?

- Is depth to groundwater contoured using **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape? This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[3] to estimate depth-to-groundwater contours across the landscape. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to contour depth to groundwater.

- *[The GSA's response states: "See Multiple Comment Subject Area Response for GDEs." However, this response does not address retaining NC dataset polygons where data gaps exist.]* The depth to groundwater contour maps (Figures 2-70 and 2-71) show large areas of data gaps, given the marked data points on the map where data exists. These maps were used to exclude all GDEs located adjacent to Chowchilla River, Ash Slough, and Berenda Slough (Figure 1 of Appendix 2.B). **As stated above, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network.**

<u>Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)</u>

[Appendix 2.B (Assessment of Groundwater Dependent Ecosystems)]

- *[No response required.]* TNC acknowledges and appreciates the comprehensive evaluation of the San Joaquin River Riparian GDE unit following our guidance, including analyzing hydrologic conditions, ecological conditions, providing an inventory of species and ecological value, along with concurrent field studies and reconnaissance. We also appreciate the use of TNC's GDE Pulse to examine NDVI and NDMI trend data for the GDE polygons within the GDE unit.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 2.2.3 Water Budget Information (p. 2-45 to 2-99)]

- *[The GSA's response states: "Evapotranspiration from groundwater by riparian vegetation is included in the evapotranspiration of native vegetation. Riparian vegetation is not included in the list of water use sectors requiring separate quantification by the GSP regulations. The GSP regulations require that outflow be quantified by water use sector defined as "categories of water demand based on the general land uses to which the water is applied, including urban, industrial,*

[3] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

agricultural, managed wetlands, managed recharge, and native vegetation." Thank you for clarifying that riparian vegetation is included in the native vegetation category.] The text states (p. 2-79): "…while for native vegetation lands, groundwater extraction by riparian vegetation was considered to be negligible because of the depth to groundwater in the subbasin." **Because there are potential GDEs included in the Chowchilla Subbasin, please quantify the evapotranspiration from groundwater by riparian vegetation even if small. Please revise the text and budget as necessary.**

Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)

[Section 3.1 Sustainability Goal (p. 3-2)]

- *[The GSA's response states: "Comment noted. The sustainability goal was discussed in public meetings and incorporates feedback received by GSAs from stakeholders during public meetings." Our comment was not addressed.]* The sustainability goal does not specifically mention beneficial uses or users of groundwater, including environmental users. It states "the six sustainability indicators, established measurable objectives, and minimum thresholds will ensure that no undesirable results of significant and unreasonable economic, social, or environmental impacts occur…" **Please rephrase the Sustainability Goal to specifically call out beneficial uses and users of groundwater including environmental users. Please state how the sustainability of environmental uses will be protected. In addition, a statement about any intention to address pre-SGMA impacts should be included.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Section 3.2.5 Measurable Objectives for Depletion of Surface Water (p. 3-21)]

- *[The GSA's response refers to the Multiple Comment Subject Area Response for ISWs. This response states in part: "While shallow groundwater levels rise and fall from wet to dry season and wet year to dry year and may become connected to surface water for shorter durations, defining an interconnected surface water – groundwater system should require that such a connection exists under a broader range of seasonal and climatic year conditions." This sentence illustrates a fundamental misunderstanding of an ISW. Our comment was not addressed.]* The GSP states (p. 3-5): "Groundwater in the GDE unit is tightly coupled with surface flow and runoff and is generally maintained at depths within the maximum rooting depth range of the dominant phreatophytic species present in the unit (see Section 2.2.2). The groundwater that is potentially accessible to the vegetation composing the GDE unit likely occurs as a shallow perched/mounded aquifer fed largely by percolation of surface flow from the San Joaquin River. As described in Section 2.2.5 [should be 2.2.2.5], it has been determined that a connection between regional groundwater and streams does not currently exist in the subbasin." However, Section 2.2.2.5 does not present evidence that ISWs do not exist in the Subbasin, and states that a historical connection between groundwater and the San Joaquin River did exist through 2008.

- *[The GSA's response refers to the Multiple Comment Subject Area Response for ISWs. This response states in part: "While shallow groundwater levels rise and fall from wet to dry season and wet year to dry year and may become connected to surface water for shorter durations, defining an interconnected surface water – groundwater system should require that such a connection exists under a broader range of seasonal and climatic year conditions." This sentence illustrates a fundamental misunderstanding of an ISW. Our comment was not addressed.]* The GSP fails to establish measurable objectives or minimum thresholds for this sustainability indicator. The existence of riparian GDEs along the streams in the basin has been identified in Appendix 2.B, and their connection to groundwater is assumed. Their occurrence in the riparian zone means that these GDEs should be considered a beneficial user of groundwater that could be affected by chronic groundwater level decline as discussed above, as well as beneficial users of surface water that could be depleted by groundwater extraction. **A more robust discussion of the known facts regarding these surface-groundwater interactions in the riparian zone should be provided. In addition, more detailed discussion regarding specific data gaps should be included.**
- *[Edits made to Section 3.2.5 (pg. 3-21) referring to Appendix 2.B address our comment.]* There is a need to evaluate and discuss potential effects on beneficial uses of surface and groundwater. In addition, the applicable state, federal and local standards for the protection of aquatic, riparian and other protected habitats should be discussed. This is necessary, at a minimum, so that the nature of the data gaps can be understood. **Please refer to Attachment C for a list of freshwater species in Chowchilla Subbasin that may be exist within ISWs. We recommend that after identifying which freshwater species exist in your basin, especially federal and state listed species, that you contact staff at the Department of Fish and Wildlife (DFW), United States Fish and Wildlife Service (USFWS) and/or National Marine Fisheries Services (NMFS) to obtain their input on the groundwater and surface water needs of the organisms on the freshwater species list. Because effects to plants and animals are difficult and sometimes impossible to reverse, we recommend erring on the side of caution to preserve sufficient groundwater conditions to sustain GDEs and ISWs. Please refer to the Critical Species Lookbook[4] to review and discuss the potential groundwater reliance of critical species in the basin.**
- *[The GSA's response states: "The GSP has determined that ISWs are not present." However, the Multiple Comment Subject Area Response for ISWs states: "While shallow groundwater levels rise and fall from wet to dry season and wet year to dry year and may become connected to surface water for shorter durations, defining an interconnected surface water – groundwater system should require that such a connection exists under a broader range of seasonal and climatic year conditions." This sentence illustrates a fundamental misunderstanding of an ISW. Our comment was not addressed.]* The analysis for ISWs should include all beneficial users of surface water that could be affected by groundwater withdrawals, including

[4] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

environmental. Refer to the San Joaquin River Restoration Program (SJRRP) that identifies instream flow needs for salmon. **Please include instream flow requirements in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

<u>Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28</u>)

[Section 3.3.1 Minimum Thresholds for Lowering of Groundwater Levels (p. 3-22)]

- *[The GSP was revised accordingly.]* Please correct the call-out on p. 3-23 to Appendix 6.D (it should be 2.B).
- *[The GSA's response states: "The GSP text, maps, and figures describe RMS sites being designated as representative of the Upper Aquifer, Lower Aquifer, or both (composite). Composite wells were minimized to the extent possible, and were only included if no other suitable RMS were available specific to the Upper or Lower Aquifer only. Nested well sites are currently being installed to fill data gaps." For clarity please add this explanation to the GSP text.]* The text states (p. 3-23): "The minimum thresholds for chronic lowering of groundwater levels are based on selection of RMS from among existing production and monitoring wells located throughout the subbasin and screened in both in the Upper and Lower Aquifers." Please clarify the text to state that wells were chosen that monitor a single aquifer, but not both at the same time (i.e. composite), if that is the intended meaning.

[Section 3.3.4 Minimum Thresholds for Degraded Water Quality (p. 3-35)]

- *[The GSA's response states: "In general, meeting municipal and domestic water quality MO/MT is expected to be protective of GDEs. It should also be noted that the GSP is not responsible for existing constituent levels or ongoing non-GSP related activities that may result in increasing constituent concentrations. As described in the GSP, there are many other agencies/programs devoted to monitoring and protection of groundwater quality, with which the GSAs plan to coordinate." For clarity please add this explanation to the GSP text.]* This Minimum Threshold does not consider water quality needs of GDEs. The text states (p. 3-36): "Protection of municipal and domestic beneficial uses is also protective of all other groundwater beneficial uses." **Please elaborate on this statement and include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Section 3.3.5 Minimum Thresholds for Depletion of Surface Water (p. 3-40)]

- *[The GSA's response refers to the Multiple Comment Subject Area Response for ISWs. This response states in part: "While shallow groundwater levels rise and fall from wet to dry season and wet year to dry year and may become connected to surface water for shorter durations, defining an interconnected surface water – groundwater system should require that such a connection exists under a broader* *range of seasonal and climatic year conditions." This sentence illustrates a fundamental misunderstanding of an ISW. Our comment was not addressed.]* The text states (p. 3-40): "Therefore, the surface water depletion sustainability criteria is not applicable to the subbasin." However, no evidence is provided in the GSP to show that a hydraulic connection between groundwater and surface water does not exist. **Following the discussion presented above for Checklist Item 26 (Measurable Objectives), please include a discussion of Sustainable Management Criteria for ISWs, including Minimum Thresholds, in the GSP. Please cite data gaps regarding ISWs and make plans to reconcile them in the Monitoring Section of the GSP.**

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 3.4 Undesirable Results (p. 3-40)]

- *[The GSA's response states: "This section, in particular Table 3-8, describes undesirable results in terms of physical groundwater parameters. How these groundwater parameters relate to beneficial uses of groundwater are described in other sections. The relation to environmental beneficial uses is described in the sections and appendix that describe the GDE analysis completed." For clarity please add this to the GSP text.]* This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses that could be adversely affected by chronic groundwater level decline. **Please add "potential adverse impacts to GDEs" to the list of potential undesirable results presented in Table 3-8 (p. 3-41).**

[Section 3.4.1 Undesirable Results for Lowering of Groundwater Levels (p. 3-42)]

- *[The GSA's response states: "GDEs are not one of the six sustainability indicators designated under SGMA and GSP regulations. However, GDEs were considered in detail in the GSP and specific GDE RMS sites incorporated in the Plan." While we do acknowledge and appreciate the comprehensive evaluation of the San Joaquin River Riparian GDE Unit in the GSP, this response does not address our comment regarding the use of management areas.]* The GSP states (p. 3-42): "Using the Fall measurements (assumed to be collected in October), a groundwater elevation undesirable result is defined to occur when greater than 30% of the RMS [representative monitoring sites] each exceed the groundwater level minimum thresholds for the same two consecutive Fall readings. Given a total of 36 RMS sites, a total of 11 or more the RMS would need to exceed MTs as defined above to constitute an undesirable result for chronic lowering of groundwater levels." The use of 30 percent to define an undesirable result does not allow for the occurrence of low water levels in one area, such as near a GDE, to be an Undesirable Result, which may impact environmental beneficial use. There are three RMS near the San Joaquin River Riparian GDE unit, which could be evaluated separately. **Please consider the use of a separate management area for the San Joaquin River Riparian GDE unit so that different sustainable management criteria can be established for this GDE unit.**

[Sections 3.4.4 Undesirable Results for Degraded Water Quality (p. 3-44)]

- *[The GSA's response states: "Arsenic is included as one of the key constituents for which MT and MO have been set. The GSP accounts for arsenic regardless of the mechanism by which the concentrations may increase, provided that increase in concentrations is caused by GSP projects/management actions." For clarity please add this discussion to the GSP text.]* This section describes undesirable results in terms of meeting drinking water standards. The following is a link to a paper by Smith, Knight and Fendorf (2018) titled "Overpumping leads to California groundwater arsenic threat": (https://www.nature.com/articles/s41467-018-04475-3). **The section should be modified to state that overpumping and dewatering of aquitards has been identified as a potential source of elevated arsenic concentrations above drinking water standards in San Joaquin Valley aquifers. In addition, any potential undesirable results from degradation of water quality that may impact GDEs and freshwater species in the area should be discussed in this section.**

[Sections 3.4.5 Undesirable Results for Depletion of Surface Water (p. 3-45)]

- *[The GSA's response refers to the Multiple Comment Subject Area Response for ISWs. This response states in part: "While shallow groundwater levels rise and fall from wet to dry season and wet year to dry year and may become connected to surface water for shorter durations, defining an interconnected surface water – groundwater system should require that such a connection exists under a broader range of seasonal and climatic year conditions." This sentence illustrates a fundamental misunderstanding of an ISW. Our comment was not addressed.]* **Following the discussion presented above for Checklist Item 26 (Measurable Objectives), please include a discussion of Sustainable Management Criteria for ISWs, including Undesirable Results, in the GSP. Please cite data gaps regarding ISWs and make plans to reconcile them in the Monitoring Section of the GSP.**

<u>Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)</u>

[Section 3.5 Monitoring Network (p. 3-45)]

- *[The GSA's response states: "There is extensive discussion in the GSP regarding groundwater levels and GDEs, and specific RMS sites were selected to represent GDEs. See Multiple Comment Response Section regarding ISWs." Please further elaborate on how monitoring data will be used to estimate the quantity and timing of streamflow depletions for ISWs, as required by SGMA.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater <u>*and related surface conditions*</u> (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of complicated factors, and this relationship is not characterized or discussed. The Monitoring Network section currently does not address future needs for ISW monitoring. In this section, please describe monitoring for ISWs as described below:

- In addition to the need for additional shallow monitoring wells in the upper aquifer to map GDEs, **there is also a need to enhancing monitoring of stream flow and vertical groundwater gradients by installing more stream gauges and clustered/nested wells near streams, rivers or wetlands.** Ideally, co-locating stream gauges with wells that can monitor groundwater levels in both the upper and lower aquifers would enhance understanding about where ISWs exist in the basin and whether pumping is causing depletions of surface water or impacts on beneficial users of surface water and groundwater. **Please provide sufficient detail for the investigation and monitoring program including stream gauges, screened intervals and frequency of monitoring, in order to describe monitoring of both the extent of ISWs and the quantity of surface water depletions from ISWs.**

[Section 3.5.1.1 Groundwater Level Monitoring Program (p. 3-47)]

- *[The GSA's response states: "Additional nested monitoring wells, including shallow Upper Aquifer wells are currently being installed. Additional analyses will be conducted related to GDEs and ISW for the 5-year update based on additional data collected during the next five years." There are large areas in the center of the subbasin where data gaps remain unfilled. Please retain GDEs located near these streams until data gaps are filled.]* As noted in our comments above on Checklist Items 11-15, the depth to groundwater contour maps (Figures 2-70 and 2-71) show large areas of data gaps, given the marked data points on the map where data exists. These maps were used to exclude all GDEs located adjacent to Chowchilla River, Ash Slough, and Berenda Slough (Figure 1 of Appendix 2.B). **Please propose additional upper aquifer wells to reconcile this data gap.**

<u>Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)</u>

[Section 4 Projects (p. 4-1)]

- *[Edits were made in Section 4 (pg. 4-1) and text on pg. 4-7 that provide an example of benefits of recharge basins. Thank you for further defining the benefits of recharge basins.]* The Subbasin area includes GDEs and ISWs that are beneficial uses and users of groundwater, and may include potentially sensitive resources and protected lands. Protection of environmental uses and users should be considered in establishing project priorities. In addition, consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**
- *[GSP edits were made in Section 4.1.1.5 (pg. 4-7) stating that in addition to the proposed projects/management actions in the GSP, it should be noted that the San*

Joaquin River Restoration Project, which reduces diversions available for irrigation, will provide a major source of new water to support GDEs along the San Joaquin River.] This section identifies many important projects; however, the descriptions of Measurable Objectives for these projects only identifies benefits to water level and storage. **Because maintenance or recovery of groundwater levels, or construction of recharge facilities, may have potential environmental benefits in many cases it would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.**

- **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
- If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting ISWs.**
- Recharge ponds, reservoirs and facilities for managed stormwater recharge can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such facilities have been incorporated into local Habitat Conservation Plans (HCPs) and Natural Community Conservation Plans (NCCPs), more fully recognizing the value of the habitat that they provide and the species they support. For projects that construct recharge ponds, **please consider identifying if there is habitat value incorporated into the design and how the recharge ponds can be managed as multiple-benefit projects that have a benefit to environmental users. Grant and funding opportunities for SGMA-related work may apply to multi-benefit projects that can address water quantity as well as provide environmental benefits.**
- For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

Attachment C

Freshwater Species Located in the Chowchilla Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Chowchilla Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the Chowchilla groundwater basin boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[5]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[6] as well as on The Nature Conservancy's science website[7].

Scientific Name	Common Name	Legally Protected Status		
		Federal	State	Other
BIRD				
Actitis macularius	Spotted Sandpiper			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	Bird of Conservation Concern	Special Concern	BSSC - First priority
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard

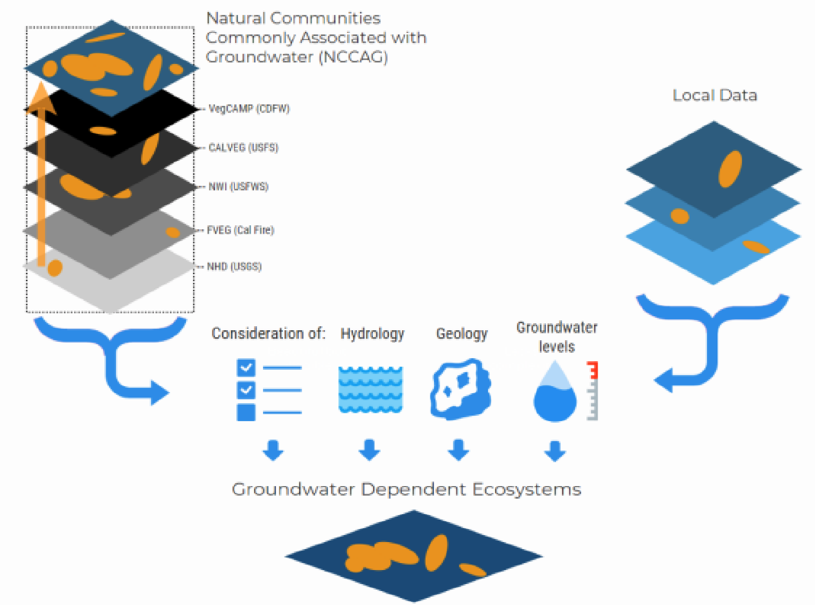
IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[8] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[9]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[8] *NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/*

[9] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[10]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[11] on the Groundwater Resource Hub[12], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

[12] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

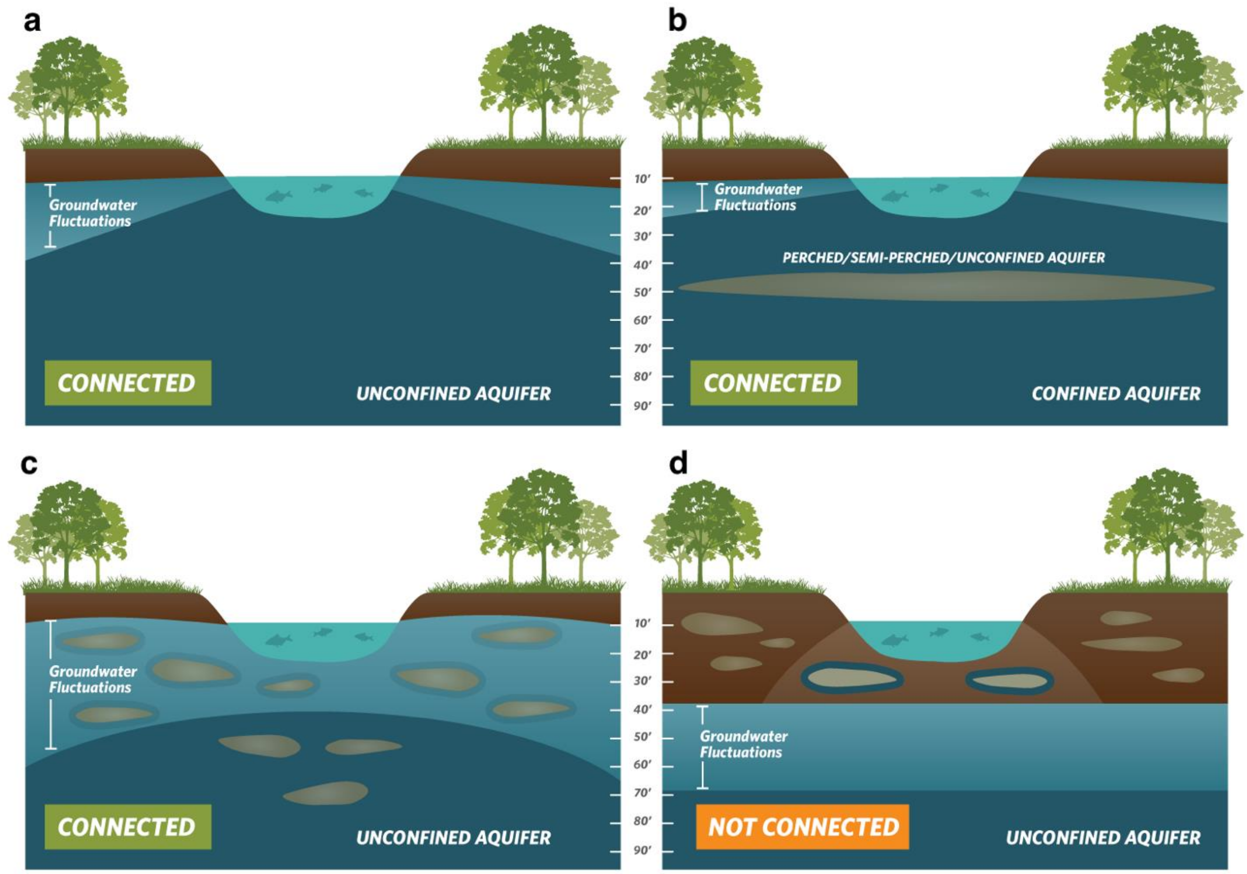

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[13] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[14] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[15] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[16]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

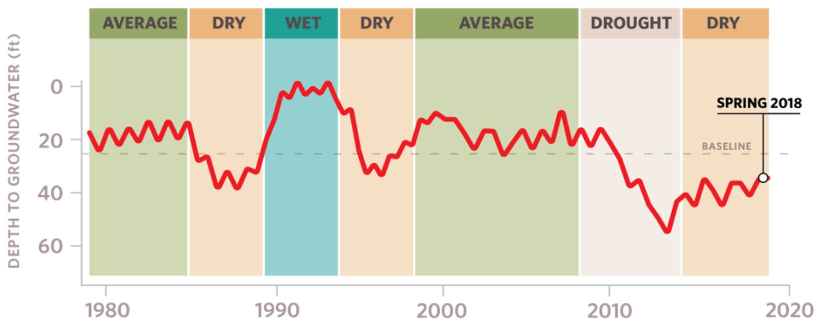

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[13] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[14] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[15] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[16] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[17], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

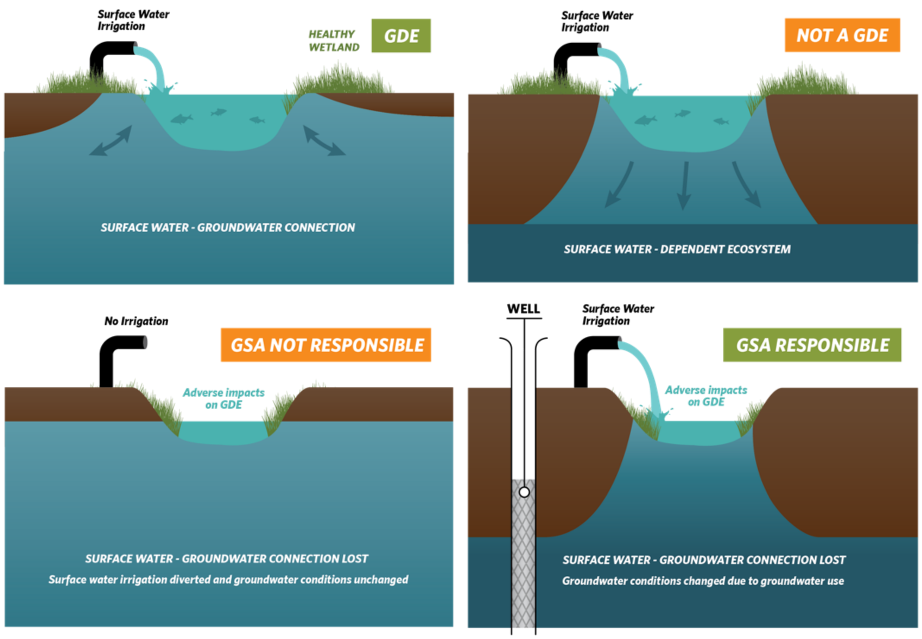

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[17] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

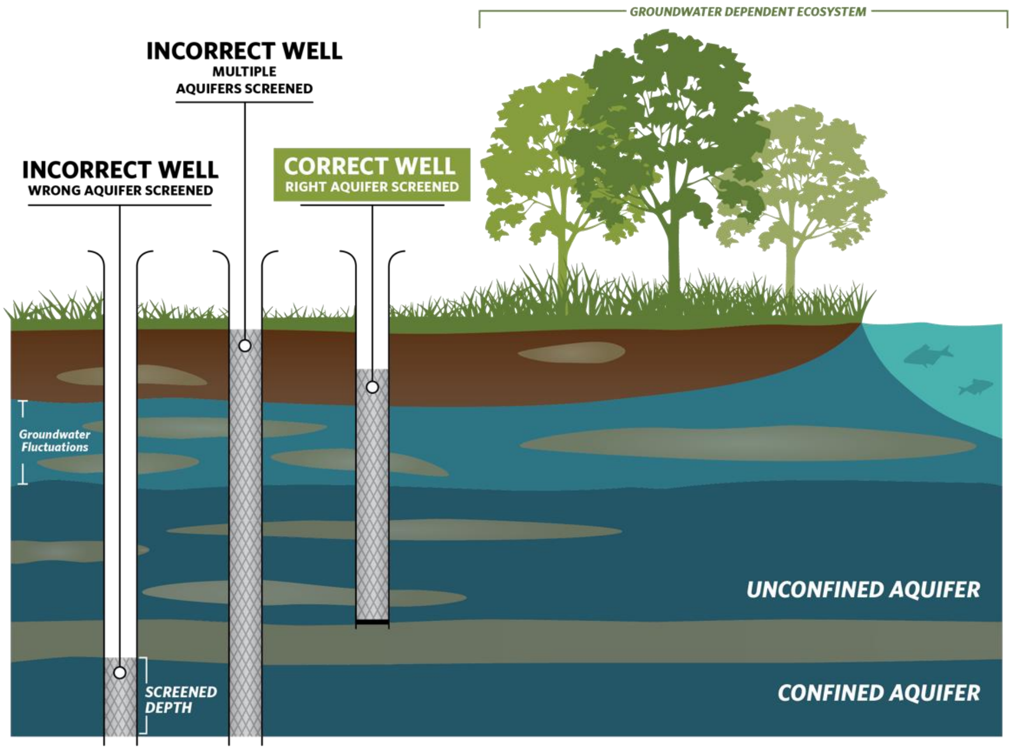

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[18] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

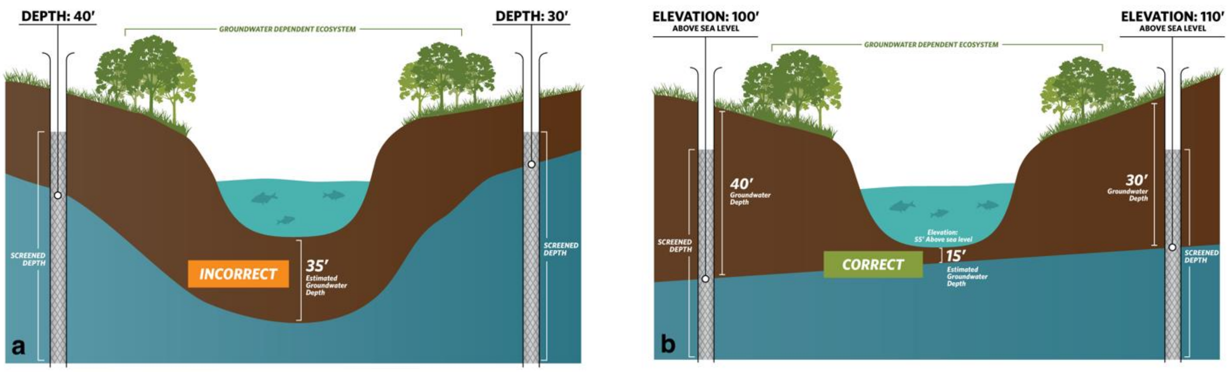

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

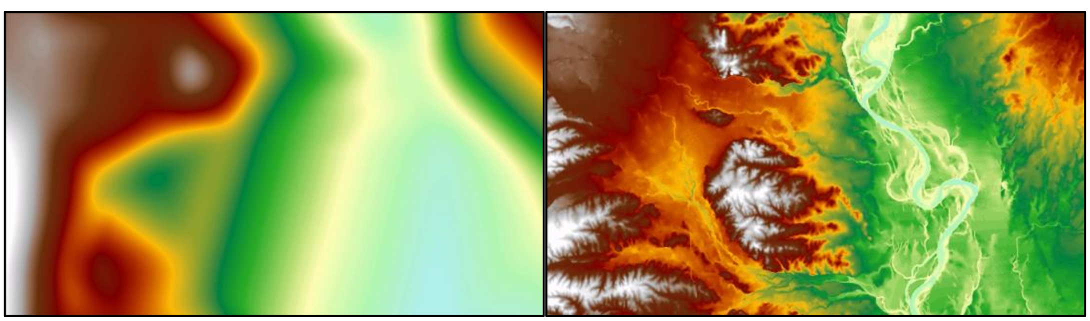

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[18] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Attachment F

The GSA Response to TNC Comments on the Draft GSP can be found on DWR’s SGMA portal as attachment 2 of 2.

Attachment G

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Grassland Groundwater Sustainability Plan (GSP), Delta Mendota Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Grassland Groundwater Sustainability Agency's (GGSA's) Grassland Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be sufficient in addressing environmental beneficial uses and users.

We would like to compliment the GGSA for their treatment of environmental beneficial users in the GSP. We believe the GGSA sufficiently addressed environmental beneficial users in this first GSP submission. In the spirit of continual improvement embedded in SGMA, we would like to offer the following input as areas for improvement in the next version of the GSP.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides a map and method summary of ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We would like to compliment Grassland GSA for distinguishing themselves as a GSA comprised of environmental stakeholders. While the GSP sufficiently addressed environmental beneficial users, there were portions of our feedback on the draft GSP that were based on best available science that were not incorporated in the final plan. TNC suggests that Grassland GSA consider our recommendations as areas for improvement in the 2025 version of the GSP. To ensure the plan is well implemented, we hope the GSA will continue to engage stakeholders to prioritize and develop management actions, as well as make plan improvements as data becomes available.

Interconnected Surface Waters – The GSP incorrectly omitted potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were described to be limited to a 9-mile-long reach of the San Joaquin River on the north edge of the San Luis National Wildlife Refuge because this is the only location where groundwater is "known to be in direct hydraulic communication with a stream." However, depth to groundwater data discussed in Sections 3.2.2.1 and 3.2.2.2 suggests that many of the managed wetlands and other surface water bodies in the Grassland Plan Area are also likely to be groundwater-connected. In addition, no data was provided proving that San Luis Creek, Los Banos Creek, Mud Slough, Salt Slough, Garzas Creek or Ortigalita Creek are not connected to the upper aquifer along some portion of the drainage for some time period. Any areas where a lack of shallow groundwater data makes the determination of ISWs uncertain should be identified as a data gap rather than being assumed to be disconnected. Our analysis of groundwater levels from 2011 to 2018 indicate that all of the streams in the GSP are connecting, including Salt Slough, Los Banos Creek, and other streams and rivers (see Attachment F). Therefore, potential may ISWs exist in the Plan Area that are not being addressed and managed in the GSP.

<u>Map and Assessment of potential ISWs</u>:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the Grassland GSP, 117.5 river miles are gaining, 49 are losing, and no streams are likely disconnected. Attachment F contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

<u>TNC recommendation:</u> Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. To help confirm interconnectivity, we suggest prioritizing obtaining additional shallow groundwater level data from the shallow monitoring wells installed by the GGSA in 2018 (and possibly installing additional shallow wells and stream gauges), and performing a thorough review of existing information on surface water-groundwater interconnectivity, including developing estimates of the quantity and timing of streamflow depletions in the Subbasin. Where data gaps exist, we recommend that the GSP describe

concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystems – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 20,079 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

We applaud the thoughtful characterization of Wetland GDEs and Vegetative GDEs in the GSA area, including the use of DWR's NC Dataset Viewer to develop GDE maps and use of a Ducks Unlimited wetland delineation dataset to further refine the maps. The GSP provides additional description of the types and extent of managed and natural wetlands, upland GDE and acreages of different types of GDEs. TNC appreciates GGSA's efforts to fully characterize and describe impacts to GDEs and to recognize the role of groundwater in the preservation of habitat and ecosystems in the largest remaining wetland in the United States.

Water Budget – We commend the Grassland Water District (GWD) and Grassland Resource Conservation District (GRCD) for having successfully managed the water budget of the area (including the groundwater budget) for several decades without undesirable results. The GSP used an analytical accounting tool to evaluate the water budget rather than a groundwater model due to a lack of available cropping and water use data in some parts of the Grassland Plan Area. Although the water budget in the GSP includes evapotranspiration (ET) as a surface water outflow, the fact that surface water outflows are greater than inflows likely due to the consumptive use of groundwater by GDEs is not described or accounted for in the model.

<u>TNC recommendation</u>: TNC recommends revisiting ET estimates in the water budget to fully account for all environmental uses of groundwater and to include the groundwater demands of native and wetland vegetation.

Sustainable Management Criteria – The GSP took steps towards including environmental beneficial users of groundwater and interconnected surface water by defining significant and unreasonable undesirable results as a reduction in habitat productivity for declines in groundwater levels. Improvement could be made to the minimum thresholds by describing how a decline in groundwater level will affect GDEs and ISWs.

<u>TNC recommendation</u>: Where, as in Grasslands, the GSP values the preservation of habitats and species that depend on groundwater and interconnected surface waters (e.g., managed wetlands, unmanaged wetlands, instream habitat, terrestrial ecosystems (phreatophytes), migratory birds, and threatened or endangered species), TNC recommends setting Sustainable Management Criteria to protect those species and ecosystems. This could be accomplished by assessing vegetation stress or some other biological metric that can monitor whether impacts are occurring to environmental beneficial users due to groundwater conditions in the basin. Please see our detailed feedback in Attachment B.

The Monitoring Network – The monitoring network could be improved to better characterize the interaction of GDEs and other environmental beneficial users of surface water and groundwater.

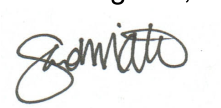
[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

Potential GDEs are located along surface water bodies where no shallow groundwater monitoring is proposed, leaving recognized data gaps unfilled.

<u>TNC recommendation:</u> TNC recommends that the GSP identify and prioritize how to reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to verify possible GDEs as groundwater dependent and reaches of ISWs. The monitoring network could also be improved by exploring how monitoring data could be used to estimate the quantity and timing of streamflow depletions.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,



Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

</table>

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Grassland Groundwater Sustainability Plan

The Grassland Groundwater Sustainability Plan (GSP), adopted December 10, 2019 as Resolution 2019-119, was reviewed by TNC. TNC submitted comments on the Public Draft GSP on November 27, 2019. Responses to comments on the public draft were not publicly available so we compared the Public Draft GSP to the Final GSP to determine whether changes were made to the Final GSP in response to TNC's comments. This attachment lists our original comments on Public Draft GSP, as submitted to the Grassland Groundwater Sustainability Agency (GSA) during the public comment period, and states [in green text in brackets] whether or not our comments were addressed in the Final GSP.

<u>Checklist Item 1 – Notice & Communication (23 CCR §354.10)</u>

[Section 2.6.1 Description of Beneficial Uses and Users (p. 2-44)]

- *[We applaud the inclusion of the information listed in our comment in the draft GSP. TNC's recommendation for further improvement (i.e., inclusion of a description of the types and extent of managed and natural wetlands and upland GDE areas in the Plan Area) was provided in Section 2.5.12 of the draft GSP.]* We applaud the inclusion of 1) environmental users of groundwater, specifically public wildlife refuges and private wetlands, in the description of beneficial uses and users of groundwater in Section 2.6.1 of the GSP; 2) a list of potential freshwater species in Table CC-7 of the Delta-Mendota Groundwater Subbasin GSP: Common Chapter (Appendix A); and a description of the types and extent of managed vs. natural wetland and upland GDE areas. Environmental stakeholders were engaged throughout the development of the GSP as described in this and other sections. The Board of Directors of the Grassland Water District (GWD) and Grassland Resource Conservation District (GRCD) consulted with California Department of Fish and Wildlife (CDFW) and United States Fish and Wildlife Service (USFWS). GWD, CDFW and USFWS hold the surface water rights used within the Grassland Plan Area. **The GSP could be further improved by including an additional description of the types and extent of managed and natural wetlands and upland GDE areas in the Plan Area.**

<u>Checklist Items 2 to 4 - Description of Plan Area (23 CCR §354.8)</u>

[Section 2.1 Plan Area, 2.2 Summary of Jurisdictional Areas, 2.3 Water Resources Monitoring and Management Programs, 2.4 Relation to General Plans (pp. 2-1 to 2-32)]

- *[We appreciate the inclusion of the information listed in our comment in the draft GSP. TNC's recommendation for further improvement (i.e., additional descriptions of how the plan relates to the requirements of other resource management plans of federal, state and local agencies that are applicable to wetlands, other GDEs and*

threatened or endangered species that may use these habitats) was provided in Section 2.2.1 of the draft GSP.] Section 2.1.2 (p. 2-4) of the GSP provides a robust description of the Grassland Ecological Area (GEA), which is recognized as a critical wetland ecosystem and consists of a combination of privately managed wetland habitat, state wildlife areas, and national wildlife refuges that provide habitat for migratory birds. A description of
    - existing land use (p. 2-7),
    - water sources and use (p. 2-9),
    - jurisdictional areas (p. 2-11),
    - existing water resource monitoring and management programs (p. 2-19), and
    - land use elements of general plans are provided (p. 2-27).

  The GSP could be further improved by including additional descriptions of how the plan may relate to the requirements of other resource management plans of federal, state and local agencies that are applicable to wetlands, other GDEs and threatened or endangered species that may use these habitats.
- *[TNC comments not incorporated.]* Section 2.4.4 (Permitting New or Replacement Wells) (p. 2-31) of the GSP describes the well permitting program adopted under Chapters 9.27 and 9.28 of the Merced County Code and managed by Merced County Department of Public Health, Division of Environmental Health (MCDEH). Although this section describes the county Groundwater Mining and Export Ordinance (Chapter 9.27) and recognizes that mining and export of groundwater may yield adverse physical impacts to beneficial users of groundwater, the plan would benefit from further description of this important groundwater management program. This Ordinance is closely aligned with the sustainability goals of this GSP, and prohibits the "mining" of groundwater (regardless of whether it is exported from the county), which is defined as *"… the process, deliberate or inadvertent, of extracting groundwater from a source at a rate or amount in excess of the replenishment rate, such that the groundwater level declines persistently, threatening exhaustion of the supply, a decline of pumping levels to uneconomic depths, land subsidence, or significant water quality or other significant environmental damage*." The Ordinance requires an applicant to provide information that issuing a permit would not violate this prohibition, and because issuing such permits is discretionary, requires review under the California Environmental Quality Act (CEQA) before a permit can be issued. **Please consider including a description of the implications of the Groundwater Ordinance regarding sustainable management of new well permits under each of the applicable SGMA sustainability indicators. In addition, we suggest adding a discussion of how future well permitting and well construction will be coordinated with the GSP under SGMA to assure achievement of sustainability goals.** The State Third Appellate District recently found that counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). **We recommend including a discussion of the need for the well permitting program to comply with this requirement.**

Checklist Items 5 to 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 3.1 Hydrogeologic Conceptual Model, 3.2 Groundwater Conditions (p. 3-1 to 3-40)]

- *[TNC comments not incorporated.]* The Hydrogeologic Conceptual Model thoroughly describes the principal upper and lower aquifers. Basin-wide cross sections provided in Figures 3-10 through 3-14 include a graphical representation of the lateral and vertical distribution of the aquifers and the Corcoran Clay aquitard that separates them. However, very little information is provided regarding how the upper aquifer may be connected to and interact with surface water and GDEs, and whether perched aquifers exist. Although direct groundwater interaction is not the primary source of water to most of the wetlands in the Plan Area, it is nevertheless an important consideration in terms of understanding how groundwater management could be optimized to support both the sustainability goals of the GSP and the mission of the GWD and GRCD to provide wetland habitat. **We suggest the GSP could be improved by providing additional descriptions of perched aquifers, interconnections between shallow groundwater and surface water and GDEs, vertical groundwater gradients, connections with the lower aquifer through the Corcoran Clay, and the resulting potential interaction of groundwater pumping with ISWs and GDEs.**
- *[TNC comments not incorporated.]* Section 3.2.2.1 (Depth to Water) (p. 3-22). The depth to groundwater in the shallow monitoring wells installed by the GGSA in 2018 ranged from 1 to 5 feet in the spring and 4 to 9 feet in the fall. Inference is made that groundwater levels in the upper aquifer are shallow enough to be directly evaporated. As such, much of the vegetation in areas of shallow groundwater in the Plan Area likely rely on shallow groundwater to meet at least a portion of its evapotranspiration demand and thus meets the definition of a GDE. Information is provided regarding the Level 4 Groundwater Development Project; a groundwater exchange program whereby private pumpers are contracted to deliver up to 29,000 AFY pumped from their wells for use in managed wetlands. In exchange, the contracted pumpers are provided surface water, to which GWD holds water rights, that can be used for irrigation. Groundwater levels in upper aquifer wells enrolled in this program that were measured in 2014 ranged from 10 to 20 feet below ground surface. The effects of this substantial program on groundwater levels, and the resulting impacts on GDEs, ISWs and the water budgets of managed wetlands should be identified. **The GSP could be improved by further describing the implication of shallow groundwater levels identified in the recently installed monitoring wells relative to GDEs and ISWs. A discussion of the effects of the Level 4 Groundwater Development Project on shallow groundwater levels, GDEs, ISWs and the water budgets of managed wetlands could also be provided.**
- *[TNC comments not incorporated.]* Section 3.2.2.2 (Water Level Elevations and Direction of Flow) (p. 3-23). Figure 3-15 shows Spring 2015 groundwater elevations as ranging from 130 feet amsl in the southwest to 70 feet amsl in the north. Groundwater flow is generally northward and converges on an apparent discharge area that extends northward along the center of the Plan Area; however, this flow field and the discharge implications of converging flow lines are not discussed. In

addition, it is unclear how these groundwater elevations relate to depths to groundwater for the shallow monitoring wells discussed in Section 3.2.2.1. **Please consider providing an explanation of current groundwater flow directions and converging flow lines along the center of the Plan Area and explain how the reported upper aquifer groundwater elevations relate to groundwater elevations measured in recently installed shallow monitoring wells. It would be helpful to discuss the implications of this information on the interaction between groundwater extraction from the upper aquifer and GDEs, ISWs and the water budgets of managed wetlands.**

- *[TNC comments not incorporated.]* Section 3.2.3 (Potential Sources of Groundwater Recharge) (p. 3-30) identifies the primary sources of recharge as groundwater inflow, seepage from water conveyance facilities, and deep percolation from wetlands. We agree that managed wetlands are a significant source of recharge in the Grassland Plan Area; however, the converging groundwater flow lines in the upper aquifer near the center of the Plan Area suggest this is an area of net groundwater discharge. **Please consider 1) elaborating on the potential relationship between recharge and discharge from the managed wetland areas, 2) providing evidence for spatial and temporal variability in recharge, 3) providing implications for shallow groundwater levels that could support GDEs and management of the wetlands, and 4) identifying any data gaps and plans to address them in the monitoring networks.**
- *[TNC comments not incorporated.]* Section 3.2.4 (Potential Sources of Groundwater Discharge) (p. 3-32) identifies the primary sources of upper aquifer discharge as pumping, groundwater outflow toward the San Joaquin River, downward percolation through the Corcoran Clay, and evaporation and evapotranspiration of shallow groundwater. No further explanation is provided. **Please identify and describe GDEs, ISWs and evapotranspiration from managed wetlands as discharge components and beneficial users.**

<u>Checklist Items 8, 9 and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)</u>

[Section 3.2.9 Interconnected Surface and Groundwater Systems (p. 3-39)]

- *[TNC comments not incorporated.]* The regulations [23 CCR §351(o)] define ISWs as "*surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted*." "*At any point*" has both a spatial and temporal component. Even short durations of interconnection between groundwater and surface water can be crucial for surface water flow and support of environmental users and uses of groundwater and surface water. ISWs can be streams, lakes, wetlands (including managed wetlands) and other surface water bodies. ISWs can be either gaining or losing. The GSP (p. 3-39) states that "*(t)he only locations in the area evaluated where groundwater is known to be in direct hydraulic communication with a stream is along a nine-mile-long reach of the San Joaquin River on the north edge of the San Luis NWR."* Groundwater contour maps from shallow monitoring wells installed nearby indicate that the river is gaining along this reach. Depth to groundwater data discussed in Sections 3.2.2.1 and 3.2.2.2 suggests that many of the managed wetlands and other surface water bodies in the Grassland Plan Area are also likely to be groundwater-connected. No data is provided in the GSP to show that San Luis Creek, Los Banos Creek, Mud Slough, Salt Slough, Garzas Creek or Ortigalita Creek are not connected to the upper aquifer along some portion of the drainage for some time period. **We suggest providing additional data or analysis to substantiate the nature of the hydrologic relationship between the upper aquifer and these additional ISWs, including the San Joaquin River, other creeks within the Plan Area, managed wetlands, and other surface water bodies. Any areas where a lack of shallow groundwater data makes the determination of ISWs uncertain should be identified as a data gap. Data used to fill the data gap could include groundwater level data from shallow or nested monitoring wells, comparison of stream stages or water surface elevation data to groundwater levels, modeling information or additional gaging data.**

Checklist Items 11 to 20 – Identifying, Mapping and Describing GDEs (23 CCR §354.16)

[Section 2.5.12 Impacts to Groundwater-Dependent Ecosystems (p. 2-40)]

- *[We applaud the Grassland GSA for identifying and mapping GDEs in this important ecosystem and recognizing the role of groundwater in habitat preservation.]* Section 2.5.12 and other sections throughout the GSP more than adequately identify, map, and describe GDEs within the Grassland Plan Area. The GSP relied on a Ducks Unlimited (DU) wetland delineation dataset to develop a Wetland GDE map (Figure 2-10) and used TNC's Natural Communities Commonly Associated with Groundwater (NCCAG) database to evaluate Vegetative GDEs (Figure 2-11). As described, many of the possible GDEs identified and mapped occur within habitat managed by GWD, GRCD, and state and federal entities within the Plan Area. The vegetative GDE map considers that all vegetation polygons identified in the NC Dataset are possible GDEs. As such, the GGSA's GSP is a model GSP that fully recognizes the role of groundwater in the preservation of habitat and ecosystems in the largest remaining wetland in the United States.
- *[No changes to GSP text made.]* Data gaps have been identified in Section 5.5.2 (p. 5-30) related to the existing monitoring network for the depletion of ISW sustainable management criterion. Limited shallow groundwater level monitoring data are available along the San Joaquin River within the Grassland Plan Area. The extensive surface water monitoring network in the managed wetlands provides a unique opportunity to better understand the interaction between groundwater pumping, shallow groundwater, surface water, and wetland vegetation. **Please consider installing additional shallow monitoring wells in the future to augment the monitoring network in this area.**

Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)

[Section 3.3 Water Budget (pp. 3-41 to 3-66)]

- *[We would like to highlight the fact that GWD and GRCD have successfully managed the water budget of the area (including the groundwater budget) for several decades* *without undesirable results. TNC recommendations were not incorporated.]* Section 3.3.1 (p. 3-41) states that an analytical accounting tool was used to evaluate the water budget rather than a groundwater model. A lack of available cropping and water use data in some parts of the Grassland Plan Area during the historical average period selected for the GSP is cited as a primary reason for this decision. While the GSP correctly states that GSP regulations do not require the use of a model if an equally effective tool can be implemented, the GSP would significantly benefit from a more robust demonstration that the analytical accounting tool is equally effective. **Please consider data to validate or calibrate the assumptions incorporated into the water budget accounting tool. A more thorough description of the tool, its development and historical use would also greatly improve this discussion. Finally, it would be helpful to note the fact that GWD and GRCD have successfully managed the water budget of the area (including the groundwater budget) for several decades without undesirable results. We believe that incorporation of these details would make the use of an analytical water budget accounting tool more likely to be accepted.**

- *[TNC comments not incorporated.]* ET is included as a surface water system outflow (p. 3-50). Surface water system outflows are reported to be greater than inflows, which is likely due to the consumptive use of groundwater by GDEs (p. 3-61). This is consistent with information in earlier sections of the GSP and our comments above that the Grassland Plan Area is characterized by extensive GDEs and ISWs. We note, however, that the ET surplus in the surface water budget is greater than the ET discharge in the groundwater budget (by up to 280% in the current water budget). **Please consider providing additional explanation of the accuracy and uncertainty of the ET estimates and identify data gaps as appropriate.**

<u>Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)</u>

[Section 4.1 Sustainability Goal (p. 4-1)]

- *[No changes to GSP text made. While the sustainability goal is written in a general way to encompass all of the GSAs within the Delta-Mendota Subbasin, we note that GGSA mentions environmental uses and users of groundwater in subsequent paragraphs within Section 4.1 (p. 4-2). In addition, the last sentence of Section 4.1 should include a reference to ISWs.]* The sustainability goal for the Delta-Mendota Subbasin reiterates regulatory requirements and does not provide a clear description of the goal relative to the Grassland Plan Area setting and beneficial uses. Beneficial uses and users of groundwater in the Plan Area are predominantly environmental, as is noted throughout the GSP, yet the goal does not specifically mention environmental uses or users of groundwater. **The GSP would benefit from better capturing the fact that the sustainability goal for the Plan Area includes ensuring that all beneficial uses and users of groundwater, including GDEs, ISWs and related critical habitats, migratory birds, and threatened or endangered species, are protected from undesirable results.**

Checklist Items 30 to 46 – Undesirable Results (23 CCR §354.26)

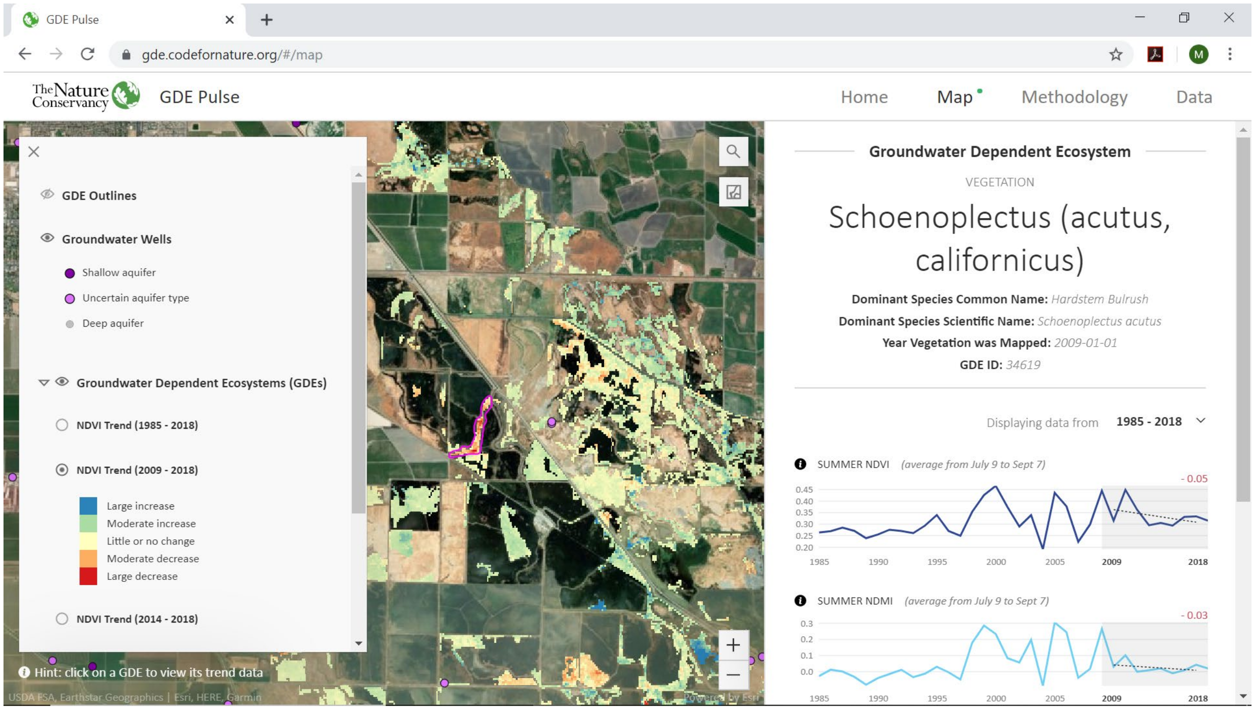
[Section 4.3.1 Undesirable Result Development (pp. 4-3 to 4-5)]

- *[TNC comments not incorporated.]* Interconnected Surface Water. The GSP states that *"(g)roundwater pumping in the Grassland Plan Area does not influence surface water depletion"* (p. 4-5) and that "*no management activities have depleted interconnected surface water in the Grassland Plan Area within the historical period*." This is presumably because groundwater pumping to maintain water levels in managed wetlands will always result in a net contribution to the wetland, even if some of the water is recaptured by the well through increased seepage, and additional surface water may be provided when available to maintain habitat productivity. In addition, the maintenance of water levels in the managed wetlands and the proximity of the San Joaquin River will help to mitigate potential effects to unmanaged wetlands, upland GDEs (e.g., alkaline meadows), or streams by maintaining high groundwater levels. **We suggest revising the discussion to further explain why significant and unreasonable impacts to GDEs and ISWs are not likely to occur.**

Checklist Items 27 to 29 - Minimum Thresholds (23 CCR §354.28)

[Section 4.3.3 Significant and Unreasonable Impacts & Threshold Exceedances Defining Undesirable Results (pp. 4-6 to 4-12)]

- *[TNC comments not incorporated.]* Minimum Thresholds for Groundwater Levels and Groundwater Storage (p. 4-7 and Table 4-1). A 20% lowering of groundwater levels below recent historical low groundwater levels during the period 2000-2019 defines an undesirable result based on impacts to environmental beneficial uses. Management actions are triggered by three years of threshold exceedance or when more than 50% of monitoring sites exceed the threshold. **The GSP would benefit from a more robust explanation of the process and rationale for selection of this threshold, and why it is considered protective of GDEs and ISWs, including managed wetlands, unmanaged wetlands, upland GDEs and ISWs. Please also consider providing additional data to substantiate this threshold, such as an assessment of vegetation stress in response to the historical low groundwater levels using TNC's GDE Pulse tool** (refer to https://gde.codefornature.org). Below is a screenshot example of data available in GDE Pulse for NC Dataset polygons found in the Subbasin.



- *[TNC comments not incorporated.]* Minimum Thresholds for Interconnected Surface Waters (p. 4-8 and Table 4-2). Significant and unreasonable undesirable results for ISWs are defined as a reduction of interconnected surface waterbodies and associated GDEs that would require a reduction in groundwater pumping. Reduction in groundwater discharge to the San Joaquin River would indicate an undesirable result since it would signal that near-surface groundwater levels are no longer being maintained, and undesirable results would adversely affect the riparian corridors along the San Joaquin River and "*groundwater dependent plant communities*" throughout the Plan Area. The threshold is set as a 20% groundwater level decline below recent historical low levels during the period 2000-2019 in 50% or more upper aquifer monitoring wells. **The GSP would benefit from a similar discussion for this sustainability indicator to that suggested above for groundwater level decline.**

[Section 4.4 Minimum Thresholds (pp. 4-14 to 4-24)]

- *[TNC comments not incorporated.]* The rationale described in Section 4.3.3 is repeated in this section and thresholds are developed for specific wells. Minimum thresholds for groundwater levels, groundwater storage (using groundwater levels as a proxy), and ISWs were developed considering the upper aquifer as the principal source aquifer for the Grassland Plan Area. Discussion regarding GDEs and ISWs is minimal, and none of the minimum thresholds directly address measurement of effects on environmental beneficial users such as ISWs or GDEs. **Since ISWs and GDEs are covered by this GSP, we recommend that for each of the applicable sustainable management criteria, the GSP includes a discussion of GDEs and ISWs and how the minimum threshold will affect them.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Section 4.5 Measurable Objectives (pp. 4-25 to 4-30)]

- *[TNC comments not incorporated.]* Section 4.5.1 (Groundwater Levels, Groundwater Storage & Interconnected Surface Water) (p. 4-25 to 4-27). Measurable objectives for chronic lowering of groundwater levels, reduction of groundwater storage and depletion of ISWs are set using groundwater levels as a proxy at the historical low groundwater levels measured between 2000 and 2019. **The GSP would benefit from a similar discussion of Minimum Thresholds and the rationale for selection of Measurable Objectives and their intended effect on GDEs and ISWs.**

Checklist Items 47-49 – Monitoring Network (23 CCR §354.34)

[Section 5.1.3 Description of Monitoring Network (pp. 5-7 to 5-22)]

- *[TNC comments not incorporated.]* The GSP proposes to use groundwater level monitoring for tracking chronic groundwater level decline, and as a proxy for groundwater storage reduction and depletion of ISWs. A set of representative wells have been selected (p. 5-8) to monitor the upper aquifer (nine wells) and lower aquifer (six wells). The GSP would benefit from the addition (now or in the future) of remote sensing data to assess the potential for significant and unreasonable impacts to GDEs or ISWs, integration of groundwater monitoring with the extensive system of surface water conditions in the area, and the construction of additional shallow monitoring wells. **Please consider adding an expanded description of how the monitoring networks may be refined in the future using these components.**
- *[TNC comments not incorporated.]* As described in Section 5.1.3.6 (p. 5-20), the analysis of impacts on ISWs will be evaluated by assessing groundwater levels across the Plan Area in the representative water level monitoring network. Flow conditions, periods of flow, variations, and other factors in the San Joaquin River reach adjacent to the Grassland Plan Area will be further evaluated using supplemental data from San Joaquin River Restoration Program shallow monitoring wells, contract surface water delivery flows from GWD, and information from MCDMGSA state and federal refuges. **It would be helpful to expand on the discussion of how new well and flow data will be used to improve ISW mapping and verify possible GDEs and ISWs.**

Checklist Items 50 and 51 – Projects and Management Actions (23 CCR §354.44)

[Section 6 Projects and Management Actions to Achieve Sustainability (pp. 6-1 to 6-8)]

- *[TNC comments not incorporated.]* As demonstrated in Section 3 of the GSP, the Grassland Plan Area is currently sustainable and not experiencing any undesirable results. The GSP describes projects currently being implemented by the GGSA to maintain sustainability and facilitate regional projects for the good of the Plan Area, agencies within the Delta-Mendota Subbasin, and other basins. The projects identify benefits to groundwater levels, groundwater storage, water quality, water supply, wetland habitats and GDEs. **Emphasizing the multiple benefits of these project may increase the likelihood of grant funding for their future implementation.**

Attachment C

Freshwater Species Located in the Delta-Mendota Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Delta-Mendota Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[2]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[3] as well as on TNC's science website[4].

Scientific Name	Common Name	Legally Protected Species

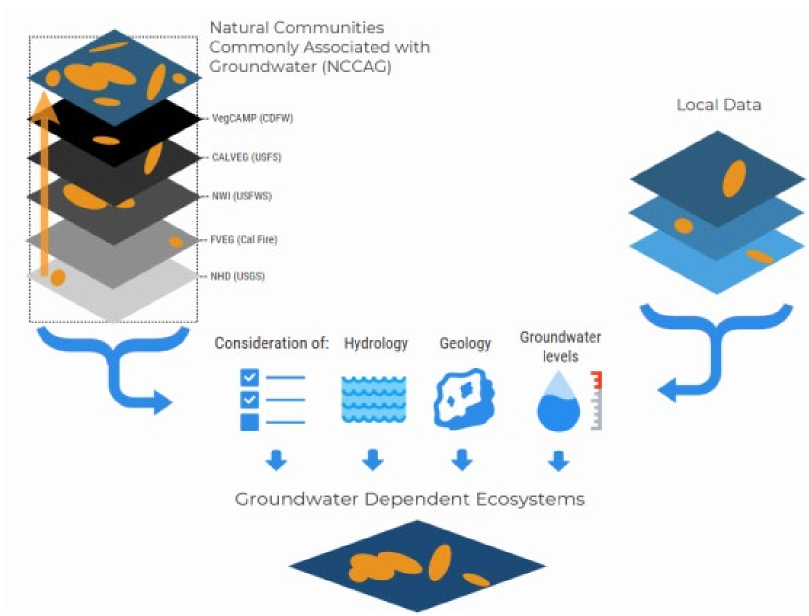
IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[5] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[6]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[5] *NC Dataset Online Viewer:* https://gis.water.ca.gov/app/NCDatasetViewer/

[6] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[7]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[8] on the Groundwater Resource Hub[9], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

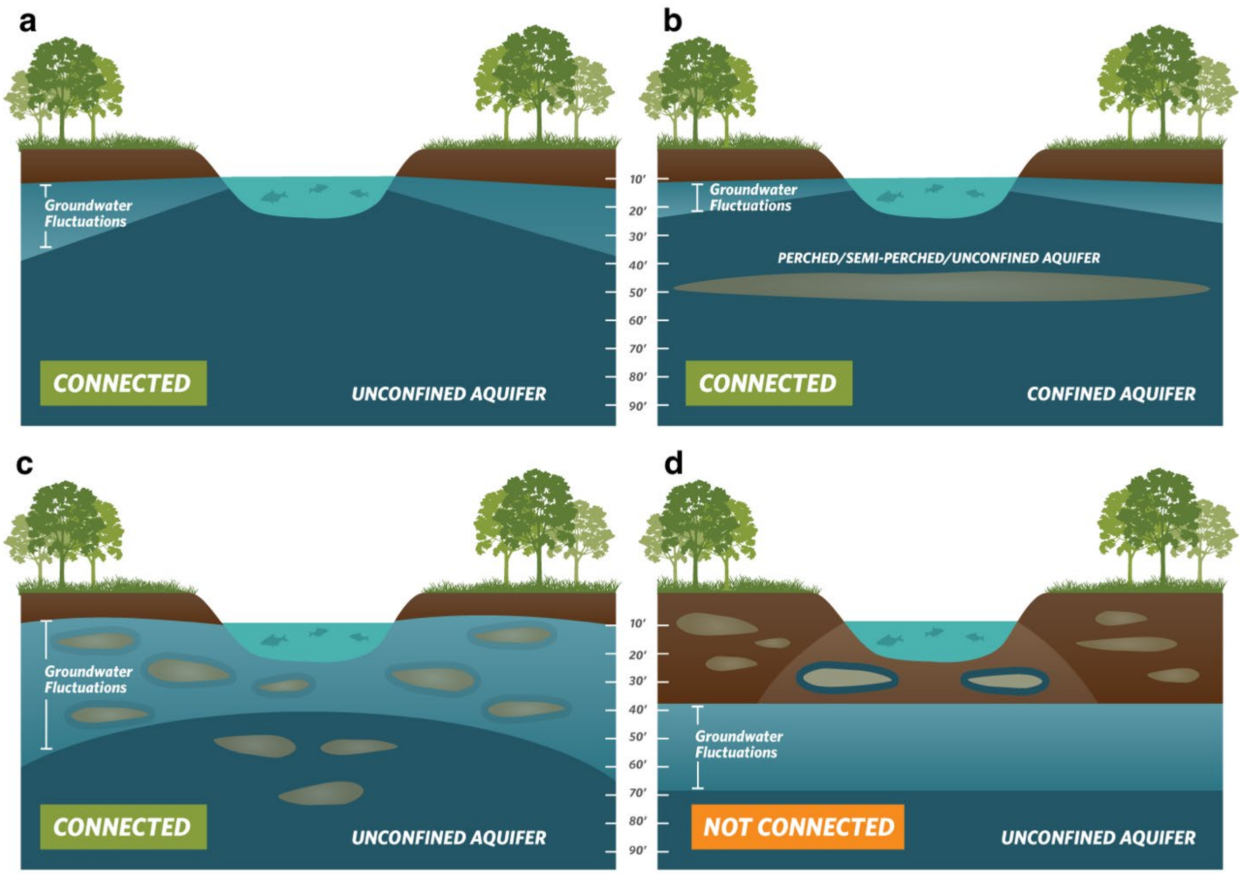

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[10] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[11] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[12] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[13]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

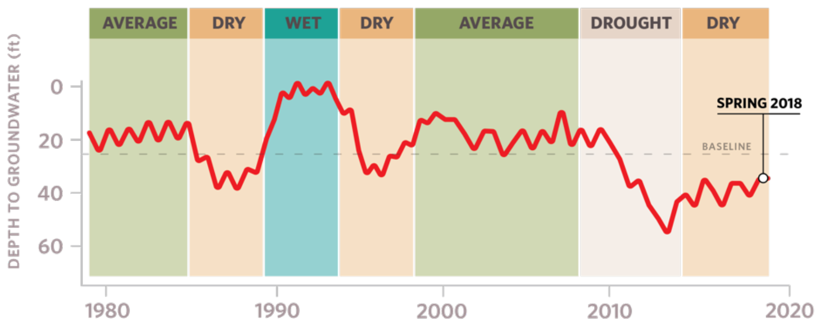

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[10] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[11] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[12] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[13] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[14], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

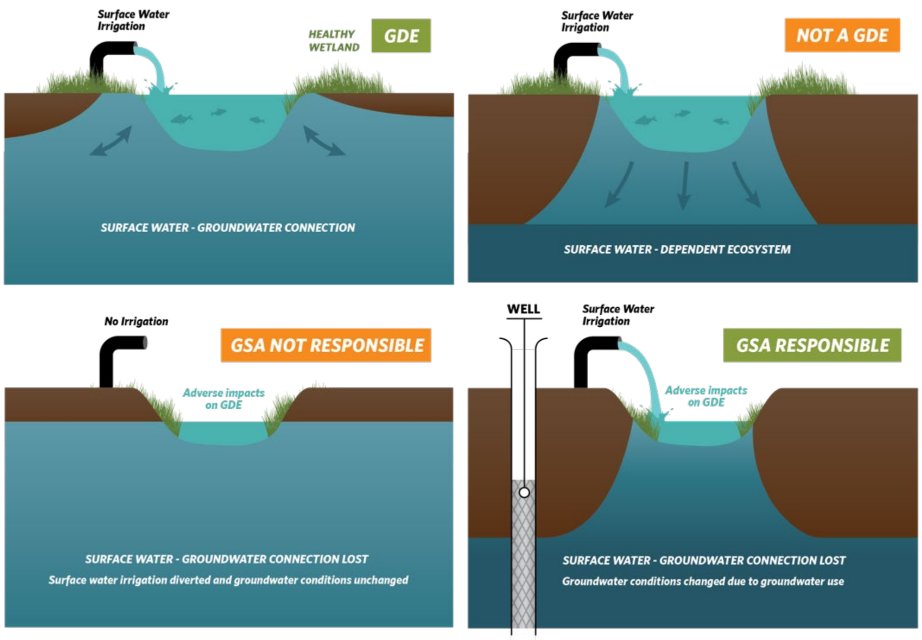

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

---

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

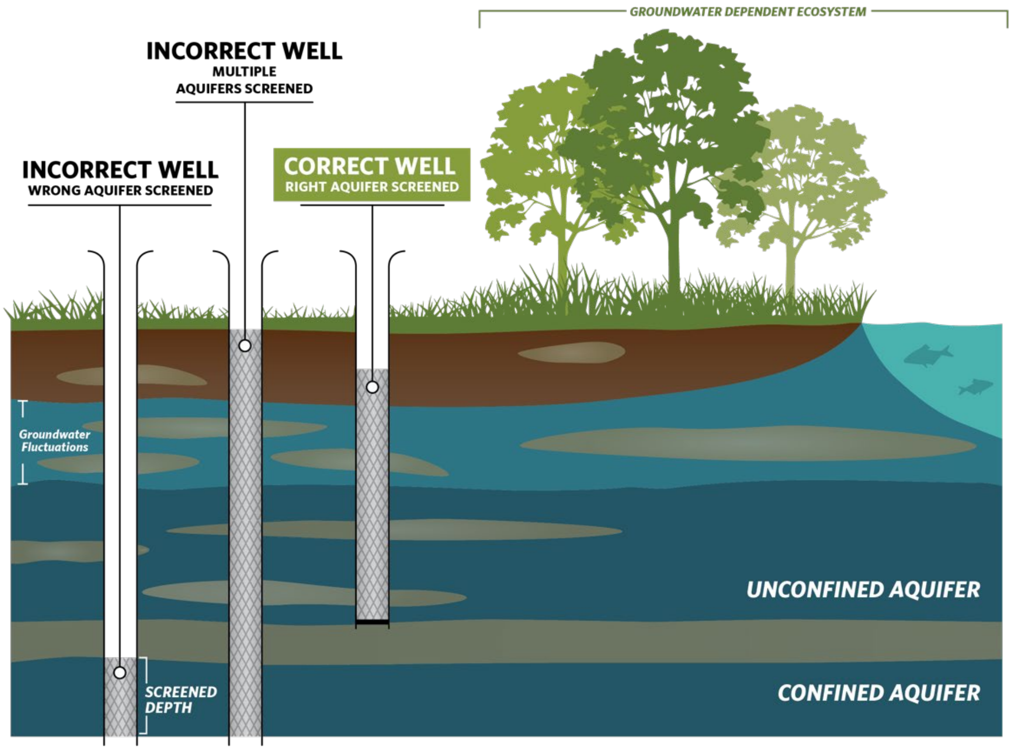

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[15] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

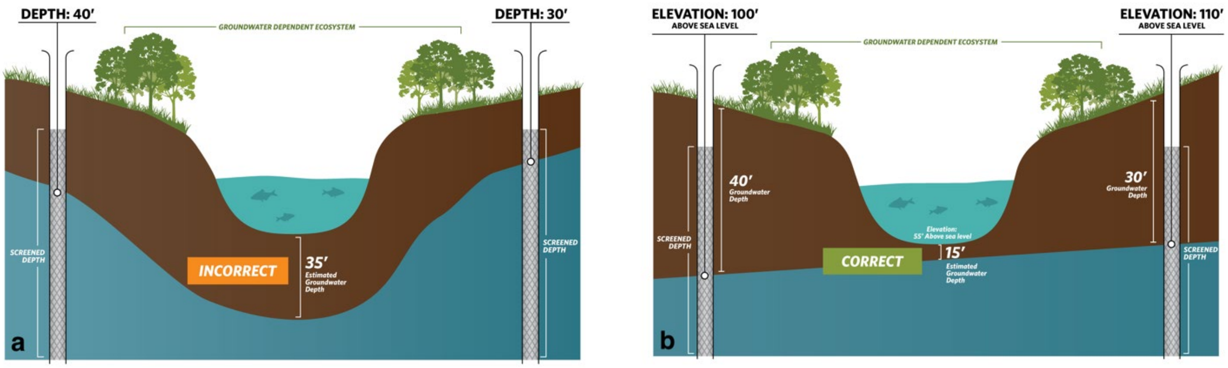

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

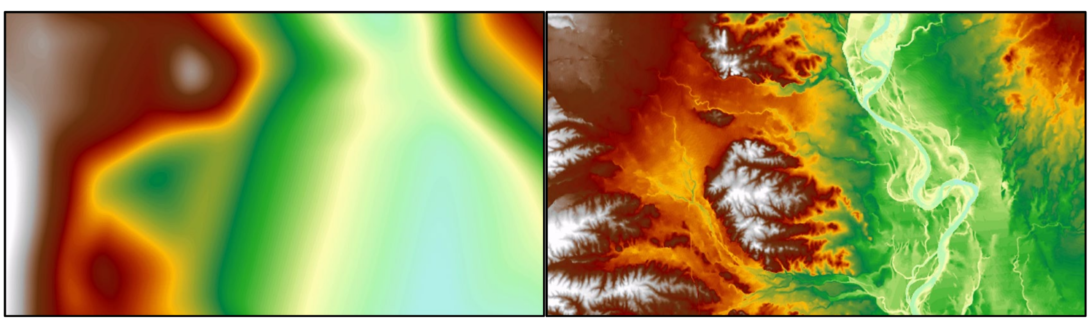

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[15] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.®

Visit
https://gde.codefornature.org/

Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[16]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[17]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Mapping Likely Interconnected Surface Water

The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:

The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

The map splits groundwater depth into four categories:

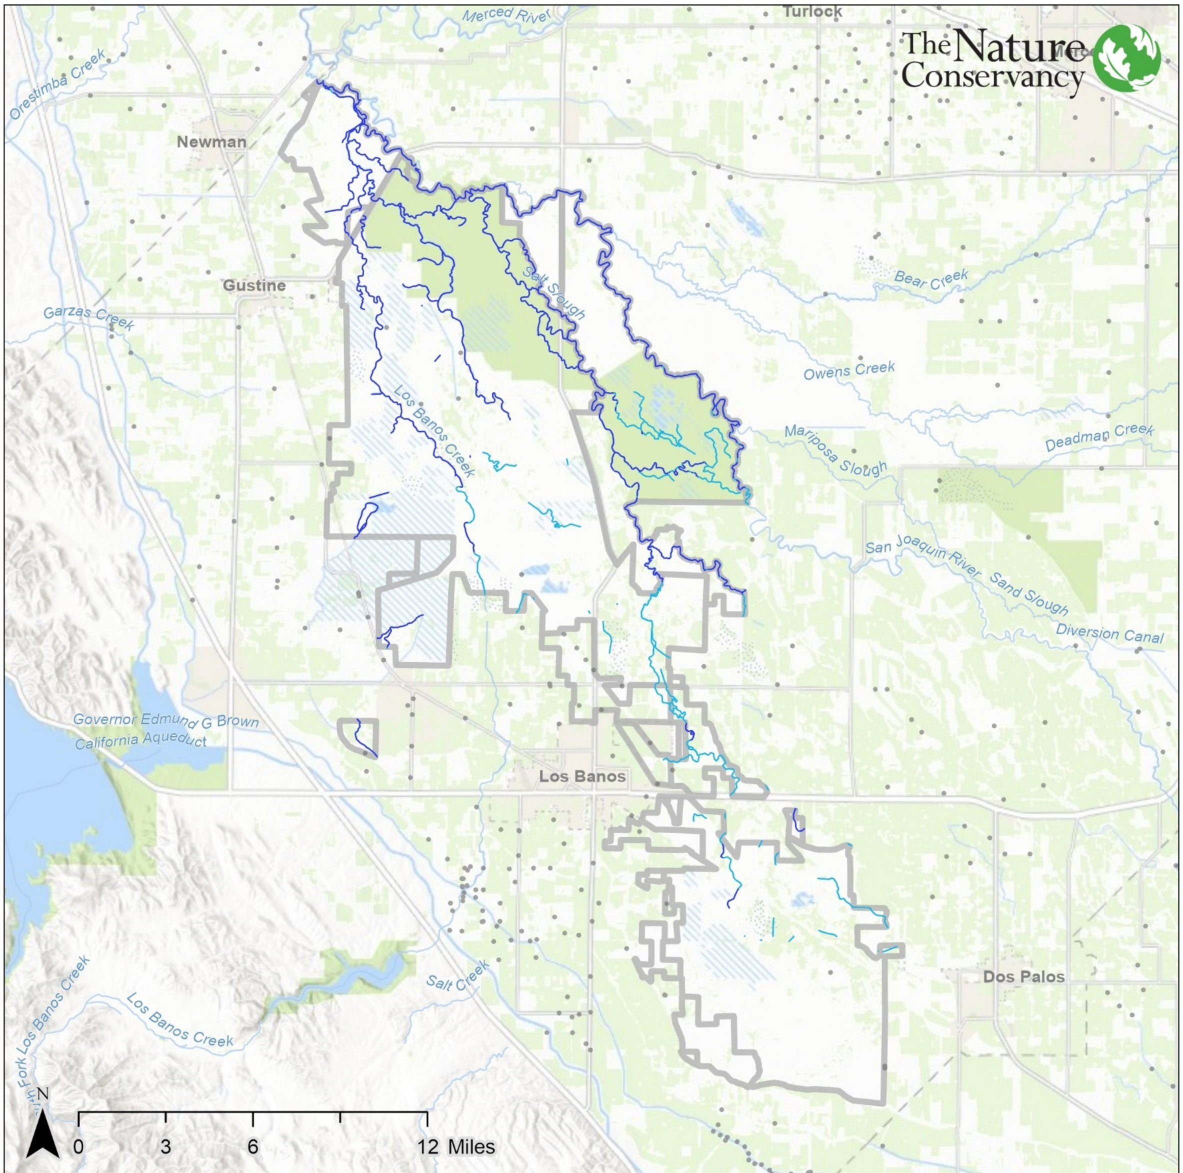
- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.

- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2011-2018)

Grassland GSA GSP



Legend

- Groundwater Sustainability Agency (GSA)
- No groundwater depth data available
- Rivers and streams with no depth data (0 miles)
- Groundwater Elevation Monitoring Point

Minimum Groundwater Depth

- Connected - Gaining: Groundwater at or above stream surface (117.5 miles)
- Connected - Losing: Groundwater within 20 feet of stream surface (49 miles)
- Uncertain*: Groundwater within 20-50 feet of stream surface (0 miles)
- Likely Disconnected*: Groundwater greater than 50 feet below stream surface (0 miles)

**Streams could be connected to riparian or perched aquifers or shallow aquifers that are poorly characterized. More data are needed to confirm disconnected status.*

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[18]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[19]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[20] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Cuyama Basin Groundwater Sustainability Plan (GSP), Cuyama Valley Basin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Cuyama Basin Groundwater Sustainability Agency's (GSA's) Cuyama Basin Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were unreasonable (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the deficiencies can be addressed now, and we encourage the Department to require these corrections prior to approval. In some case, it may be difficult to address deficiencies within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that deficiencies are due to data gaps, that these data gaps be addressed in time to inform the 2025 update. SGMA's success is contingent upon avoiding undesirable results. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of potential ISWs.

<u>Our Key Considerations</u>

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as none of our 31 comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

<u>TNC recommendation</u>: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – We are pleased to see that the GSP identified ISWs, including providing depletion by reach. Improvements should be made to map the gaining and losing reaches, identify environmental users of surface water, and to account for the spatial and temporal variations in stream depletions that are inherent with California's Mediterranean climate. These components are necessary to assess whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). Please see our detailed feedback in Attachment B.

<u>Map and Assessment of potential ISWs</u>:
By assessing groundwater elevation data from the Cuyama Basin GSA, The Nature Conservancy has determined that within the Cuyama Basin GSP, 75.2 river miles are gaining, 21.2 are losing, and the rest are uncertain or likely disconnected. Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth from measurements taken between Fall and Spring 2019.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 2,708 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under*

SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not to adequately identify, map and consider GDEs. We believe that this constitutes gaps in meeting plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on the following:

- The GDE identification process did not take groundwater levels into consideration. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface". There is no way to know if these conditions exist unless groundwater levels are taken into account.
- The GDE identification process utilized aerial imagery in an incorrect manner. The GSP relied on aerial imagery to detect surface water, and then made the assumption that only GDEs present in inundated areas were connected to groundwater. This approach is incorrect for two reasons: 1) not all surface water is connected to groundwater, and 2) visually inspecting aerial imagery cannot detect 'groundwater occurring near the ground surface'. GDEs can rely on groundwater for some or all its water requirements, whether or not surface water is present. In California, GDE reliance on groundwater often vary by season, and depend on the availability of alternative water sources (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow).
- The removal of GDE units based on the presence of sandy, dry, and friable soils was not scientifically justified. The presence of this soil type does not preclude the possibility that the dominant plant species observed are reliant on groundwater at depths below the ground surface.

<u>TNC recommendation</u>: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in our Attachment D, which provides best practices for utilizing the NC Dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We would like to commend the GSP for including the groundwater demands of native vegetation in the historical, current and projected water budgets.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

[1] *Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf*

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize groundwater level conditions that can impact environmental beneficial users of groundwater (i.e., GDEs) and of surface water (e.g., freshwater aquatic species). Potential GDEs are located along surface water bodies where no shallow groundwater monitoring is proposed; therefore, GDEs are not being specifically addressed by the monitoring network in the GSP. Furthermore, the Cuyama River is not gaged inside the Cuyama Basin, so river flows in the Basin have been estimated based on measurements at downstream gages. Installation of more stream gages is necessary for the improvement of numerical model accuracy for the estimation of interconnected surface water depletion.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data and stream gage data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Attachment A

Considering Nature under SGMA: A Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
		If NC Dataset *was* used:	The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
		If NC Dataset *was* used:	GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
	2.2.3 Water Budget *23 CCR §354.18*	Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
Sustainable Management Criteria	**3.2 Measurable Objectives** *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
Sustainable Management Criteria	**3.3 Minimum Thresholds** *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
Sustainable Management Criteria	**3.3 Minimum Thresholds** *23 CCR §354.28*	Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
Sustainable Management Criteria	**3.3 Minimum Thresholds** *23 CCR §354.28*	Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
Sustainable Management Criteria	**3.4 Undesirable Results** *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
Sustainable Management Criteria	**3.4 Undesirable Results** *23 CCR §354.26*	If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
Sustainable Management Criteria	**3.4 Undesirable Results** *23 CCR §354.26*	If hydrological data *are available* within/nearby the GDE	Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the Cuyama Basin Groundwater Sustainability Plan

A complete draft of the Cuyama Basin Groundwater Sustainability Plan (GSP), adopted in December 2019, was reviewed by TNC. Responses to comments are provided in Appendix 1D of the Final GSP. The response to comments is also provided in Attachment F of this letter. We reviewed the responses to comments and the text of the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft Final GSP, as submitted to the GSA during the public comment period, and states whether or not they were addressed in the Final GSP *[as green text within brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

1.3.1 Description of Beneficial Uses and Users of Groundwater (p. 1-46 & 1-47)

[The GSA's response does not address our comment and no changes to the GSP text were made.] [Checklist item #1]: Environmental users of groundwater, including groundwater dependent ecosystems (GDEs), are acknowledged as beneficial users of groundwater in the GSP. Other species that depend on interconnected surface waters exist in Cuyama Basin and therefore should be identified and described. For any species that are no longer present in the basin, please provide scientific rationale and data to support this claim.

The information on environmental users in the Cuyama basin is readily available and includes the data and data sources. **Please refer to the following**:

- Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), which is provided by the Department of Water Resources and identifies potential GDEs - https://gis.water.ca.gov/app/NCDatasetViewer/
- In Fall 2018, The Nature Conservancy sent a list of freshwater species located in the Cuyama Basin, which is included as **Attachment C** of this letter. Please take particular note of the species with protected status.
- In addition to identifying and describing environmental beneficial users, SGMA requires that beneficial users be considered throughout the plan. The Nature Conservancy has identified each part of the GSP with this requirement. That list is available here: https://groundwaterresourcehub.org/importance-of-gdes/provisions-related-to-groundwater-dependent-ecosystems-in-the-groundwater-s. Please ensure that environmental beneficial users are addressed accordingly throughout the plan.

2.1.6 Basin Boundaries – Bottom of the Cuyama Basin (p. 2-26)

[The GSA's response does not address our comment and no changes to the GSP text were made.] [Checklist item #5]: It is currently unclear how existing well depths compare with the depth of the upper member of the Morales Formation. According to DWR's Hydrogeologic Conceptual Model BMP[2], "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** This will prevent

[2]Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf

the possibility of extractors with wells deeper than the basin boundary from claiming exemption of SGMA due to their well residing outside the vertical extent of the basin boundary.

2.1.7 Principal Aquifers and Aquitards (p. 2-26)

[The GSA's response does not address our comment and no changes to the GSP text were made.] [Checklist item #6]: In paragraph 1, "The aquifer is considered to be continuous and unconfined with the exception of locally perched aquifers resulting from clays in the formation". **Please provide more details on:**

- the location of perched aquifers
- whether perched aquifers are being used by domestic shallow wells, GDEs and/or are potentially interacting with surface water
- the vertical gradients between the perched aquifers and the recent and younger alluvium aquifers
- other aquifer characteristics that may be known (e.g., perched aquifer thickness, porosity, hydraulic conductivity)

2.2.8 Interconnected Surface Water Systems (p. 2-112)

[The GSA's response does not address our comment and no changes to the GSP text were made.] [Checklist item #8]: The model results are demonstrating that the entire river is an interconnected surface water system ("surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" 23 CCR §351(o)). Based on the annual average stream depletion by reach (Table 2-2), it appears that losing and gaining reaches of the Cuyama can be mapped. **Please distinguish the gaining and losing reaches.** The data provides seems to indicate:

- Gaining: Reach 1, Reach 3, Reach 6, Reach 8, Reach 9.
- Losing: Reach 2, Reach 4, Reach 5, Reach 7

2.2.9 Groundwater Dependent Ecosystems (p. 2-117)

SGMA requires that all beneficial uses and users, including GDEs, be considered in the development and implementation of GSPs (Water Code §10723.2). The GSP Regulations include specific requirements to identify (map) GDEs and consider them when determining whether groundwater conditions are having potential effects on beneficial uses and users. SGMA also requires an assessment of whether sustainable management criteria (including minimum thresholds and measurable objectives) may cause adverse impacts to beneficial uses, including GDEs, and that monitoring networks are designed to detect such impacts. Therefore, mapping GDEs is a critical first step for incorporating environmental considerations into GSPs.

[Checklist item #11]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* It appears that the preliminary desktop analysis, completed by Woodard & Curran and documented in Appendix D of the draft GSP, resulted an excessive elimination – totaling two-thirds – of the NC dataset polygons mapped in the Cuyama Basin. In particular, the methods and field verification approach described in the draft GSP failed take groundwater levels into consideration. SGMA defines GDEs as "ecological communities and species that depend on *groundwater emerging from aquifers or on groundwater occurring near the ground surface*". **We recommend that depth to groundwater contour maps are used to verify whether a connection**

to groundwater exists for polygons in the NC Dataset. **Please refer to Appendix D of this letter for best practices for using groundwater data to verify a connection to groundwater.**

More specific comments related to the desktop analysis approach (as described in Appendix D of the GSP) include:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Inundation visible on aerial imagery – This method is inappropriate because it is not possible to know whether surface water is connected with groundwater by visually inspecting it with aerial imagery. For example, in some cases surface water can be completely disconnected from groundwater, so in this scenario this approach would falsely suggest that NC dataset polygons are connected to groundwater. Similarly, if surface water is not present, this method would also falsely suggest that NC dataset polygons are not connected to groundwater if plant communities and the species they support are accessing groundwater beneath the surface. This method also fails to account for the fact that GDEs can rely on groundwater for some or all its water requirements, which in California often vary by season, and depend on the availability of alternative water sources (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow).
    - If aerial imagery is to be used, a range of dates should be selected to reflect the California's Mediterranean climate, seasonal variations and water year types.
    - Phreatophytes (groundwater-dependent vegetation) often rely on groundwater that is occurring near the ground surface via their rooting network. Because these sources of groundwater are not detectable using aerial imagery, the images should be compared with contoured groundwater levels to determine whether groundwater levels are close enough to vegetation root zones.
    - We suggest the methods be revised and clarified accordingly.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Saturation visible on aerial imagery could indicate many different conditions, including standing water or saturated soils that may be ephemeral, intermittent, or permanent in nature. To help verify what the images actually indicate, this method should be coupled with more advanced remote sensing methods. Please clarify if this was the case.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Dense riparian and/or wetland vegetation visible on aerial imagery can help identify potential GDEs but is not an appropriate method to screen for whether a polygon is supported by groundwater and in fact a GDE. The presence of sparse vegetation also does not preclude the possibility that vegetation are using groundwater. Many desert and semi-arid environments with sparse vegetation can still be groundwater dependent ecosystems.

More specific comments related to the GDE field validation approach (as described in Appendix D of the draft GSP):

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The removal of Probable Non-GDE 1 and Probable Non-GDE 2 was based on the presence of sandy, dry, and friable soils was not scientifically justified. The presence of this soil type does not preclude the possibility that the dominant plant species observed are reliant on groundwater at depths below the earth surface. For example, a rooting depth of 13 feet has been observed for Ericameria nauseosa and >4 feet for Eriogonum fasiculatum, and the capillary fringe associated with those rooting networks could be accessing groundwater from deeper depths, depending on the hydraulic conductivity of the substratum. For more rooting depth data, please refer to TNC's global rooting depth database, available at: https://groundwaterresourcehub.org/gde-tools/gde-rooting-depths-database-for-gdes/

[Checklist items #12 & 13]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Decisions to remove, keep, or add polygons from the NC dataset into a basin GDE map should be based on best available science in a manner that promotes transparency and accountability with stakeholders. Any polygons that are removed, added, or kept should be inventoried in the submitted shapefile to DWR, and mapped in the plan. **We recommend revising Figure 2-64 to reflect these requirements.**

[Checklist item #17]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Groundwater conditions within GDEs should be briefly described within the portion of the Basin Setting Section where GDEs are being identified. Please refer to **Attachment E** of this letter for details on a new, free online tool that enables groundwater sustainability agencies to assess historical and current trends of growth and moisture content in vegetation using 35 years of satellite imagery for all of the polygons in the NC dataset.

[Checklist item #19]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Not all GDEs are created equal. Some GDEs may contain legally protected species or ecologically rich communities, whereas other GDEs may be highly degraded with little conservation value. Including a description of the types of species (protected status, native versus non-native), habitat, and environmental beneficial uses (see Worksheet 2, p.74 of GDE Guidance Document) can be helpful in assigning an ecological value to the GDEs. Identifying an ecological value of each GDE can help prioritize limited resources when considering GDEs as well as prioritizing legally protected species or habitat that may need special consideration when setting sustainable management criteria.

<u>3.2.1 Undesirable Results Statements - Chronic Lowering of Groundwater Levels (p. 3-2) and 3.3.1 Evaluation of Presence of Undesirable Results – Chronic Lowering of Groundwater Levels (p. 3-6)</u>

[Checklist items #30-46]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Identification of Undesirable Results – significant adverse impacts to GDEs can occur if 30% of representative monitoring wells fall below their minimum groundwater elevation thresholds for two consecutive years. The proposed approach could work if management areas were established to "identify different minimum thresholds, measurable objectives, monitoring, or projects and management actions based on differences in water use sector, water source type, geology, aquifer characteristics, or other factors" [23 CCR §351(r)]. But, as it is written now, significant and unreasonable adverse impacts to GDEs could occur if the exceedance of minimum thresholds disproportionately occurs in representative monitoring wells close to GDEs (e.g., 3 out of the 60 wells minimum thresholds are exceeded for 3 years are causing adverse impacts to GDEs, but because the definition of undesirable results (18 out of 60 wells) is not met, there is no formal recognition that undesirable results are occurring). **We recommend that groundwater levels that are protective of GDEs be considered when establishing minimum thresholds for groundwater levels across the basin. Please refer to Step 2 of *GDEs under SGMA: Guidance for Preparing GSPs*[1] for more details.**

3.2.6 Undesirable Results Statements - Depletions of Interconnected Surface Water (p. 3-5) [Checklist items #30-46]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Under the Potential Effects of Undesirable Results subsection, "If depletions of interconnected surface water were to reach Undesirable Results, groundwater dependent ecosystems could be affected" **should also include potential effects on environmental surface water users, land uses (e.g., fishing/hunting, hiking, boating), and property interests (e.g., privately and publicly protected conservation lands and open spaces, including wildlife refuges, parks, and natural preserves) [23 CCR §354.26(b)(3)].** Please also provide more details on how these various beneficial users could be adversely affected. SGMA also requires that depletions of interconnected surface water also consider adverse impacts on beneficial uses of surface water [23 CCR 354.28(6)].
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* In addition to identifying GDEs in the basin, The Nature Conservancy recommends identifying beneficial users of surface water, which include environmental users. This is a critical step, as it is impossible to define "significant and unreasonable adverse impacts" without knowing *what* is being impacted, nor is possible to monitor ISWs in a way that can "identify adverse impacts on beneficial uses of surface water" [23 CCR §354.34(c)(6)(D)]. For your convenience, we've provided a list of freshwater species within the boundary of the Cuyama Basin in **Attachment C**. Our hope is that this information will help your GSA better evaluate and monitor the impacts of groundwater management on environmental beneficial users of surface water. We recommend that after identifying which freshwater species exist in your basin, especially federal and state listed species, that you contact staff at the Department of Fish and Wildlife (DFW), United States Fish and Wildlife Service (USFWS) and/or National Marine Fisheries Services (NMFS) to obtain their input on the groundwater and surface water needs of the organisms on the freshwater species list, and how best to monitor them. Because effects to plants and animals are difficult and sometimes impossible to reverse, we recommend erring on the side of caution to preserve sufficient groundwater conditions to sustain GDEs and ISWs.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please also provide more details on when, where, and how**

groundwater changes can adversely affect these various beneficial users. Are there particular species, with legal protection, that already have known thresholds that need special consideration? The more specific the definition of what an adverse impact to beneficial users of groundwater and surface water looks like, the easier it is to quantify minimum thresholds, measurable objectives, and interim milestones that are protective of that definition.

<u>3.3.6 Evaluation of the Presence of Undesirable Results - Depletions of Interconnected Surface Water (p. 3-8)</u>
[Checklist items #30-46]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please be more specific on what measurements were used to show that groundwater gradients along interconnected surface water bodies in the Cuyama basin are not in an undesirable condition.** How were these gradients determined?
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Analysis of Interconnected Surface Waters in Section 2.2.8, particularly Table 2.2, demonstrate that depletions of interconnected surface water are occurring, meaning that adverse impacts to beneficial uses and users could be occurring. **Thus, it is inadequate to state that "depletion of interconnected surface water is not identified to be in an undesirable condition" without evaluating potential effects to beneficial users.**

<u>4.5.4 Groundwater Level Monitoring Network – Representative Monitoring (p. 4-41 & 4-42)</u>
[Checklist items #47-49]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please identify which representative monitoring wells are capable of monitoring groundwater level conditions that can impact environmental beneficial users of groundwater (i.e., GDEs) and of surface water (e.g., freshwater aquatic species).** Refer to Best Practice #4 in Attachment D to this letter for technical guidance.

<u>4.10 Depletions of Interconnected Surface Water Monitoring Network (p. 4-66)</u>
[Checklist items #47-49]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **The improvement of numerical model accuracy for the estimation of interconnected surface waters should also include the installation of clustered or nested wells and the installation of shallow monitoring wells around GDEs and the Cuyama River to resolve data gaps that were identified in Section 2.2.10**:
    - The Cuyama River is not gaged inside the Cuyama Basin, so flows of the river in the Basin have been estimated based on measurements at downstream gages.
    - Vertical gradients in the majority of the Basin are not understood due to the lack of wells with completions of different depths located near each other.
    - GDEs could be evaluated in greater detail

- Information about many of the wells in the Basin is incomplete, and additional information is needed regarding well depths, perforation intervals and current status.
- Due to sporadic monitoring by a variety of monitoring entities, a long period of record of monitoring groundwater levels does not exist in many areas in the Basin.

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please identify appropriate biological indicators that can be used to monitor potential impacts to environmental beneficial users due to groundwater conditions. Refer to Appendix E of this letter for an overview of a free, new online tool for monitoring the health of GDEs over time.**

<u>5.2.2 Minimum Thresholds, Measurable Objectives, and Interim Milestones - Chronic Lowering of Groundwater Levels (p. 5-6 thru p. 5-9)</u>
[Checklist items #26-29]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Selecting thresholds by using groundwater elevation measurements closest to (but not before) January 1, 2015 is inadequate for identifying minimum thresholds or measurable objectives. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions fails to capture the seasonal and interannual variability typical of California's climate. Hydrology is not static. Measurable objectives are intended to be set with enough operational flexibility to permit seasonal and interannual fluctuations that occur in California. **We recommend that you consider using a baseline approach to better capture seasonality and water year types.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* January 1, 2015 was at the height of California's historic drought, a period of time that was characterized by adverse impacts to domestic well owners (e.g., dry wells), GDEs (e.g., water stress impacts on growth, reproduction, and even mortality due to lack of groundwater), and surface water users (e.g., lower streamflows). **The onus is on the GSA to determine whether groundwater conditions (due to groundwater pumping) exacerbated impacts to these beneficial users. And if so, to recognize these impacts and establish thresholds and measurable objectives that can avoid adverse impacts to beneficial users caused by groundwater in all water year types.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* While total well depth information is helpful in considering adverse impacts to beneficial users of groundwater (e.g., domestic, irrigation, and municipal wells), it fails to consider adverse impacts to GDEs and environmental beneficial users of surface water in interconnected surface waters. **Environmental beneficial users of groundwater need to be considered when establishing measurable thresholds, measurable objectives, and interim milestones. Please refer to Step 2 of *GDEs under SGMA: Guidance for Preparing GSPs*[1] for how this can be accomplished.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please describe any differences between the selected minimum**

threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs, as required [23 CCR §354.28 (b)(5)].

5.7 Minimum Thresholds, Measurable Objectives, and Interim Milestones - Depletions of Interconnected Surface Water (p. 5-26)
[Checklist items #26-29]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **It is highly doubtful that January 1, 2015 surface water conditions can be considered "normal" (2nd sentence in 2nd paragraph); please provide data to substantiate this claim.** January 1, 2015 was at the height of California's historic drought, a period of time that was characterized by adverse impacts to domestic well owners (e.g., dry wells), GDEs (e.g., water stress impacts on growth, reproduction, and even mortality due to lack of groundwater), and surface water users (e.g., lower streamflows).
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please provide more data and an elaborated description on how current basin conditions have not varied from January 1, 2015 conditions.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Even if current basin conditions may not have varied from January 1, 2015, **the onus is on the GSA to determine whether groundwater conditions are causing any adverse impacts to beneficial users. And if so, to recognize these impacts and establish thresholds and measurable objectives that can avoid adverse impacts to beneficial users caused by groundwater in all water year types.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* According to Table 2-2 in the Draft GSP, 5994 AF of surface water was depleted in 2017:

Reach	Depletion in AF
2	19.9
3	300.4
4	67.8
5	906
7	4700.3
Total	**5994.4**

  Please investigate whether these depletions in surface water are adversely impacting instream flow conditions and groundwater levels in riparian areas for environmental beneficial users, especially legally protected species.

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please describe any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters [23 CCR §354.28 (b)(5)].**

7. Projects and Management Actions (p. 7-1)
[Checklist items #50 - 51]:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Please describe how the projects described in this chapter and their benefits will help "maintain a sustainable groundwater resource for beneficial users of the Basin", including environmental users, as stated in the sustainability goal for the Cuyama Basin.
- *[No response required.]* For more case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

Attachment C

Freshwater Species Located in the Cuyama Basin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Cuyama Basin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[4] as well as on The Nature Conservancy's science website[5].

Scientific Name	Common Name	Legal Protected Status		
		Federal	State	Other
BIRDS				
Actitis macularius	Spotted Sandpiper			
Agelaius tricolor	Tricolored Blackbird	Bird of Conservation Concern	Special Concern	BSSC - First priority
Anas americana	American Wigeon			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron			
Aythya collaris	Ring-necked Duck			
Butorides virescens	Green Heron			
Calidris alpina	Dunlin			
Calidris mauri	Western Sandpiper			
Calidris minutilla	Least Sandpiper			
Chen caerulescens	Snow Goose			
Cistothorus palustris palustris	Marsh Wren			
Egretta thula	Snowy Egret			
Empidonax traillii	Willow Flycatcher	Bird of Conservation Concern	Endangered	
Fulica americana	American Coot			
Gallinago delicata	Wilson's Snipe			
Haliaeetus leucocephalus	Bald Eagle	Bird of Conservation Concern	Endangered	
Himantopus mexicanus	Black-necked Stilt			
Limnodromus scolopaceus	Long-billed Dowitcher			
Megaceryle alcyon	Belted Kingfisher			
Numenius americanus	Long-billed Curlew			
Pelecanus erythrorhynchos	American White Pelican		Special Concern	BSSC - First priority
Phalacrocorax auritus	Double-crested Cormorant			
Phalaropus tricolor	Wilson's Phalarope			
Porzana carolina	Sora

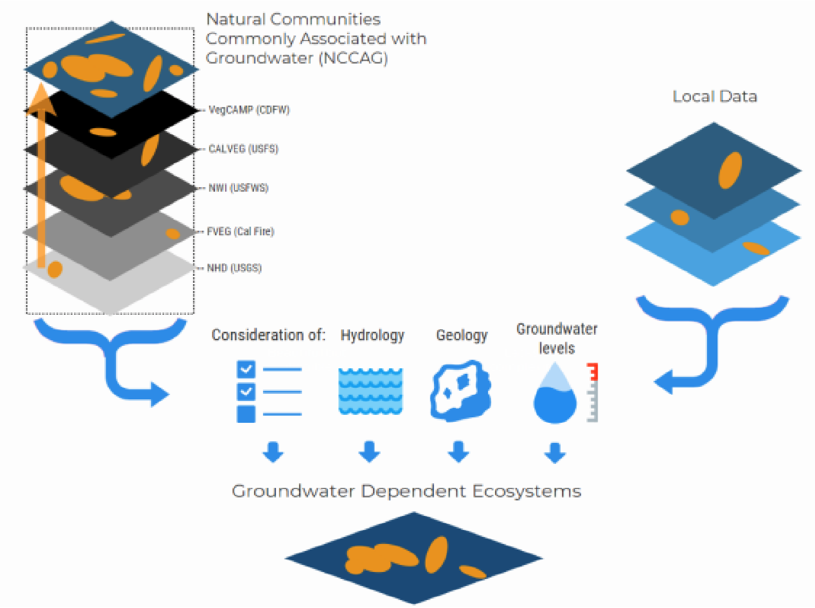
IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[6] *NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/*

[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

[10] The Groundwater Resource Hub: www.GroundwaterResourceHub.org

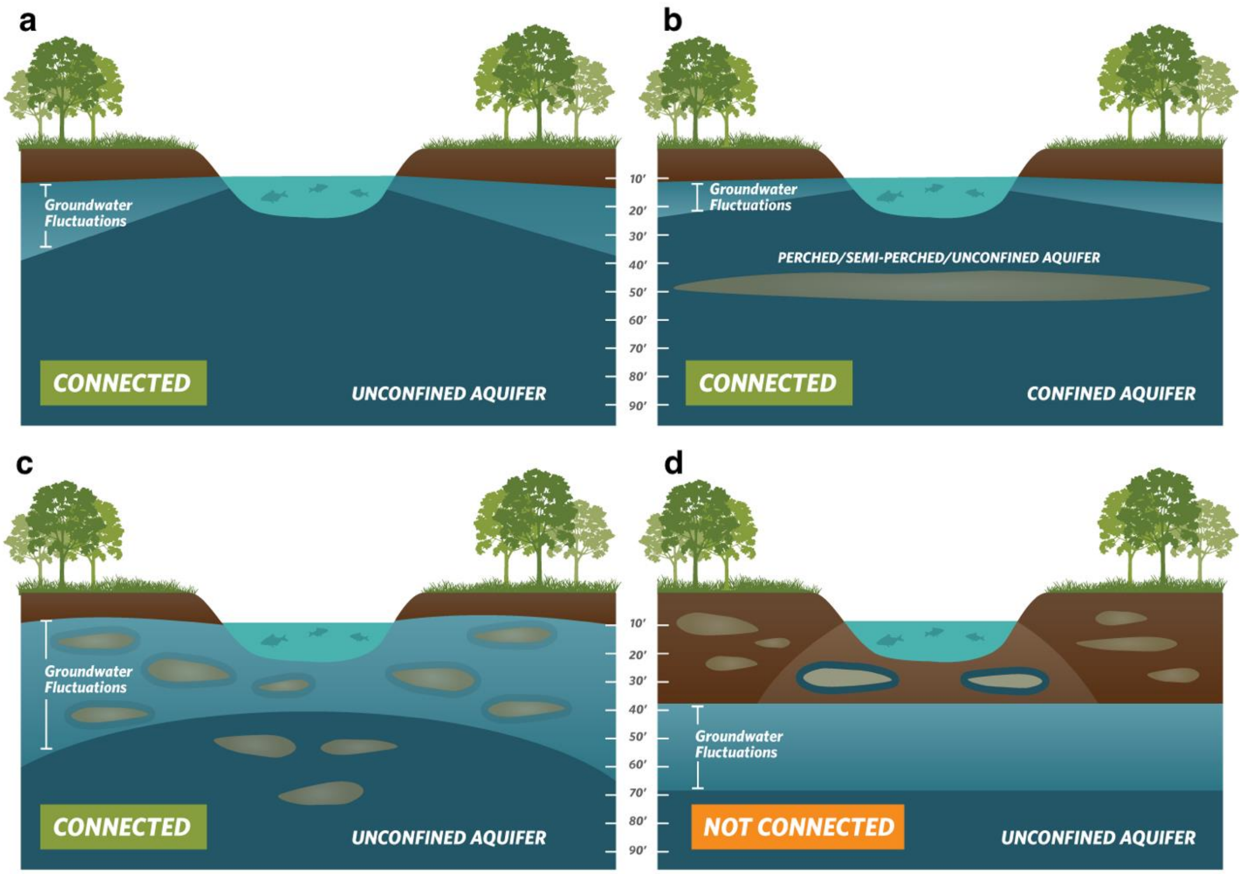

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

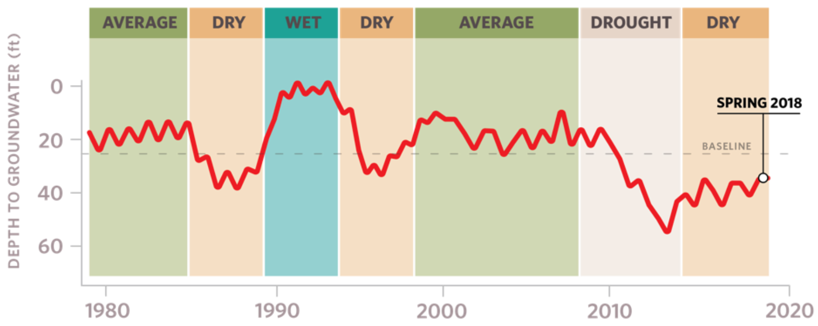

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

---

[11] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

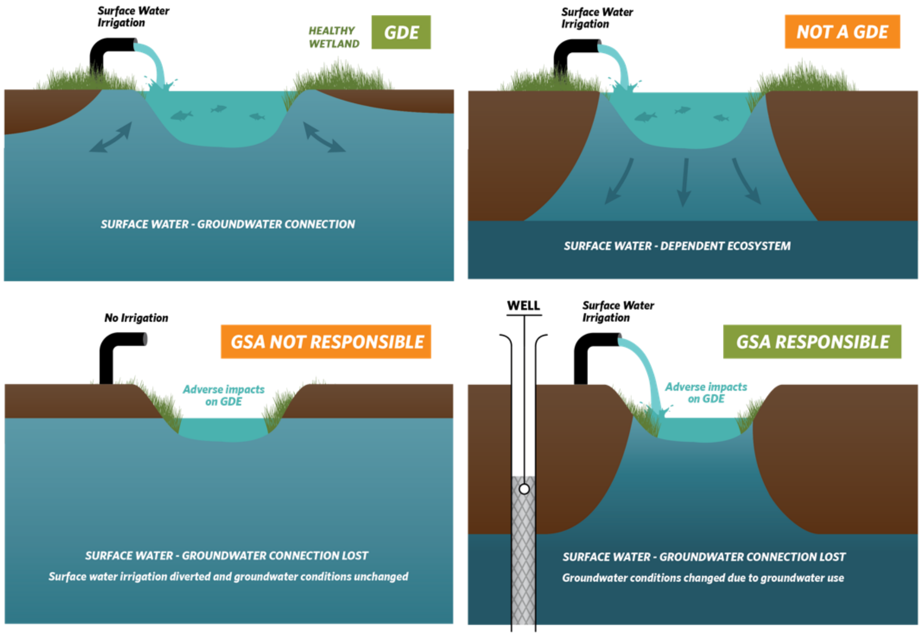

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

---

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

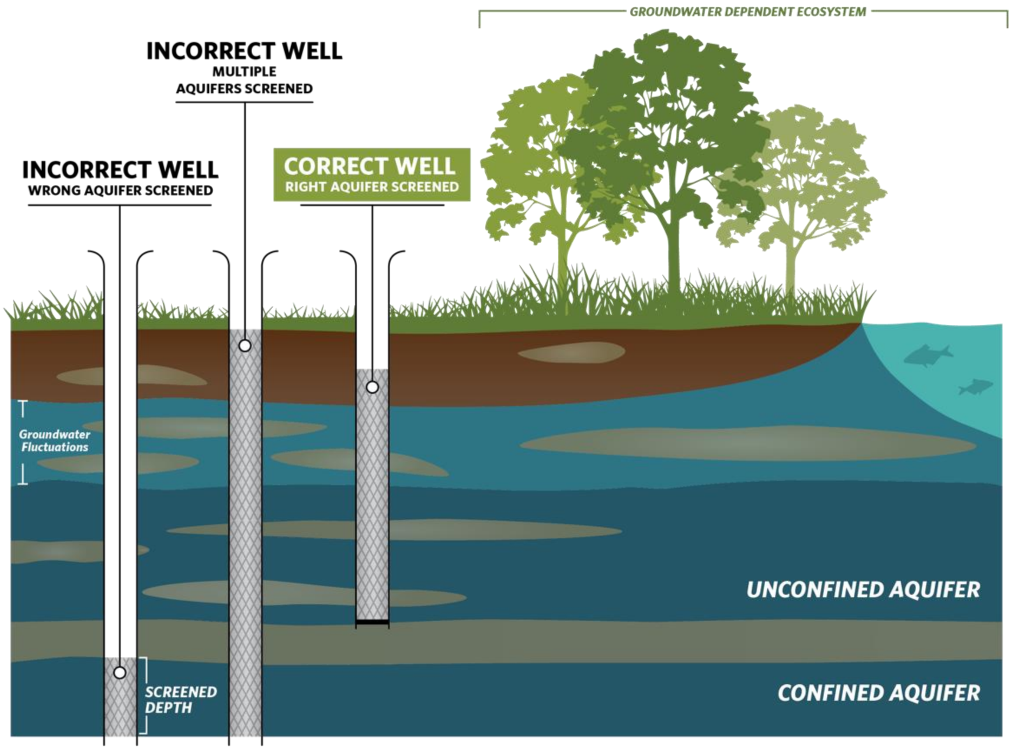

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

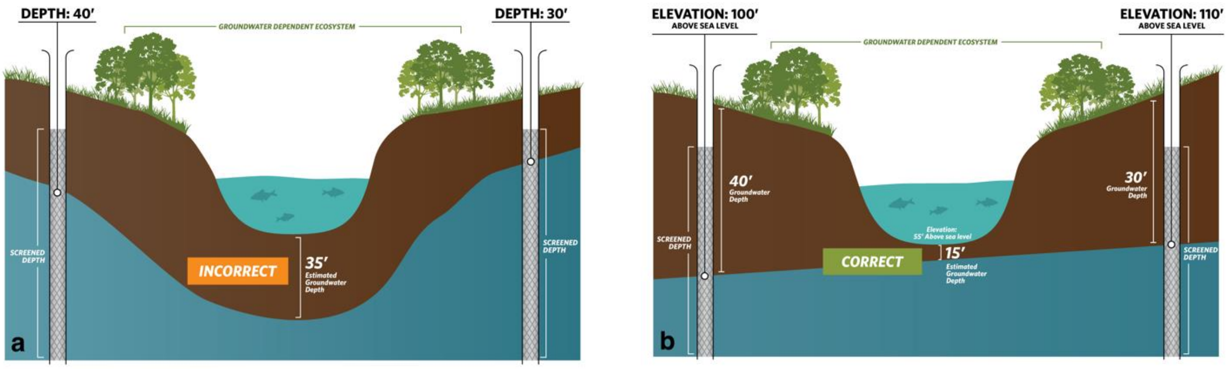

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

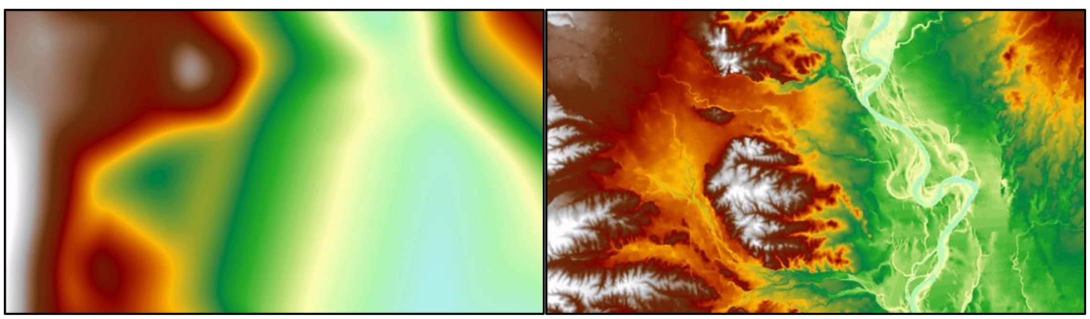

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

16 USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

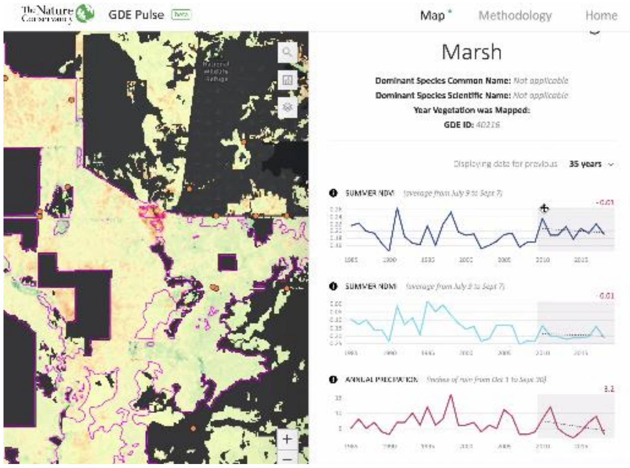
GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Attachment G

Mapping Likely Interconnected Surface Water

The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:

The groundwater elevation data, available for Spring and Fall 2019, comes from the Cuyama Basin Groundwater Sustainability Agency. These data are continuous raster layers, developed from groundwater measurements and topographic features, that approximate groundwater elevation. These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

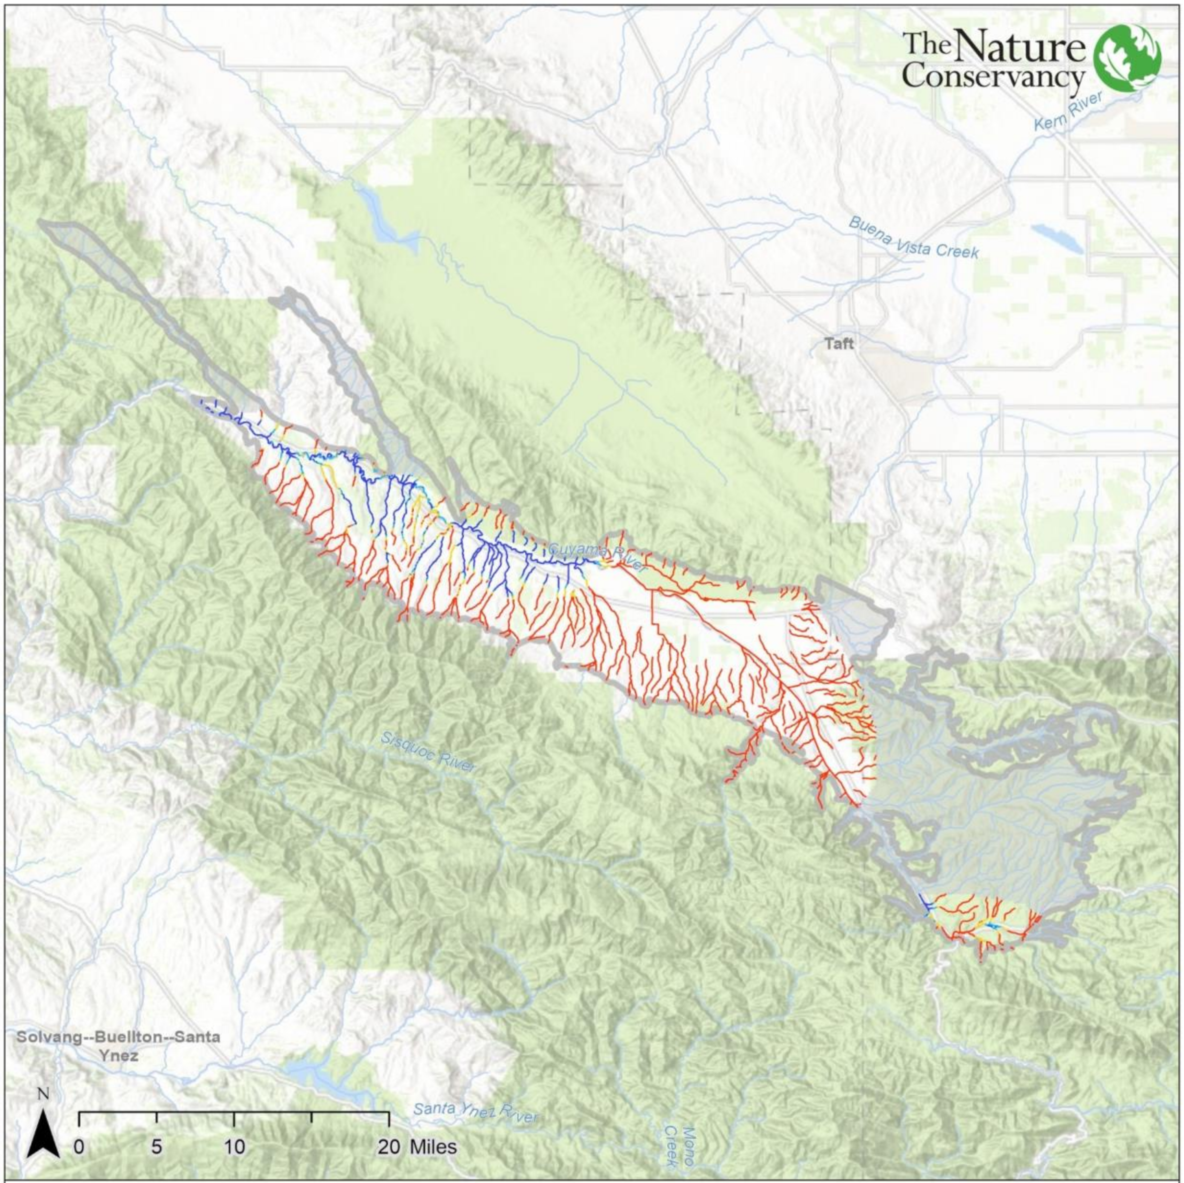
The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2019)

Cuyama Basin GSP



Legend

- Groundwater Sustainability Agency (GSA)
- No groundwater depth data available
- Rivers and streams with no depth data (330.3 miles)

Minimum Groundwater Depth

- Connected - Gaining: Groundwater at or above stream surface (75.2 miles)
- Connected - Losing: Groundwater within 20 feet of stream surface (21.2 miles)
- Uncertain: Groundwater within 20-50 feet of stream surface (28.8 miles)
- Likely Disconnected: Groundwater greater than 50 feet below stream surface (355.1 miles)

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Eastern San Joaquin Subbasin Groundwater Sustainability Plan (GSP)

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Eastern San Joaquin Groundwater Authority (ESJGWA) Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be incomplete in addressing environmental beneficial uses and users.

While the GSP addressed environmental beneficial users in some respects, our review finds that portions of the GSP should be remedied before being approved. Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that they be addressed in time to inform the 2025 update.

Our review found that the sustainability goal, undesirable results, minimum thresholds and measurable objectives (collectively, the SMC) largely or completely neglected to reasonably consider impacts to environmental beneficial users (23 CCR §355.4(b)(4)) and/or employ the best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow for further significant reductions in groundwater storage and associated groundwater levels, without consideration for negative impacts to GDEs and/or ISWs. This could result in irreparable harm to environmental beneficial users, including vulnerable species subject to state and federal laws, and undermine the intent of SGMA to achieve sustainability.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment D provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment E provides the GSA's response to TNC's comments on the Draft GSP. Attachment F provides a map and method summary of possible ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been largely ignored in the final plan, as only 10 out of 58 of our comments on the draft GSP were addressed. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience, the GSP did not "adequately respond(d) to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

TNC recommendation: We strongly recommend that the GSA prioritize stakeholder engagement through improvements to the stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)).

ISWs were evaluated by comparing monthly groundwater elevations from the historical calibration of the Eastern San Joaquin Water Resources Model to streambed elevations to identify interconnected gaining and losing streams. The GSP determined whether or not a stream reach is interconnected based on whether modeling indicated the interconnection existed more than 75 percent of the time. However, limiting the extent of ISWs based on intermittent connection is not consistent with the regulations (23 CCR §351(o)), which define ISWs as "surface water that is hydraulically connected *at any point* by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted." (emphasis added) "At any point" has both a spatial and temporal component. Even short durations of interconnection between groundwater and surface water can be crucial for surface water flow and support of wetlands. Using temporal cut-off method, particularly when identifying ISWs is recognized as a data gap, will not adequately protect the environmental beneficial uses of surface water from significant and unreasonable adverse impacts related to groundwater extraction.

Map and Assessment of potential ISWs:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the ESJGWA GSP, 25.7 river miles are gaining, 164.6 are losing, and the rest are uncertain or likely disconnected (based on streams with available groundwater depth data). Attachment G contains a one-page method summary and a GSP-specific map of ISWs.

The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018. TNC's analysis (Attachment F) of ISW indicates that additional ISW exist on the North and South Mokulumne Rivers around Staten Island, and on the Mokulumne River near Lodi. These and other areas are not included in the results from the Eastern San Joaquin Resources Model.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs and prioritize the installation of additional shallow wells at locations near high value or sensitive resources that are vulnerable to significant and unreasonable adverse impacts. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystems – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 31,010 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not adequately identify, map and consider GDEs. We believe that this falls short of meeting plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on the following:

- GDEs were rejected on the basis that groundwater levels were greater than 30 feet at a single point in time. This is approach is inconsistent with the best available science because groundwater levels fluctuate over seasons and between years due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30 feet or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unprotected in the GSP.

TNC recommendation: Request that the GSA use groundwater levels that represent interannual and inter-seasonal variability and utilize additional information provided in our guidance document (Attachment C) to identify and consider GDEs throughout the GSP. Specifically, the GSA should use Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment C.

Water Budget – We would like to commend the Eastern San Joaquin Subbasin GSP for including the groundwater demands of wetlands, GDEs, native vegetation and riparian vegetation in the

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

historical, current and projected water budgets as part of "Refuge, Native, and Riparian Evapotranspiration."

Sustainable Management Criteria – The GSP took steps towards addressing environmental beneficial users in the SMCs, however, the plan should be improved to describe potential effects on all environmental users of groundwater and interconnected surface waters, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). Undesirable results related to depletions of interconnected surface waters are defined and evaluated only for major streams and rivers. This assessment should be extended to smaller creeks and streams that the GSP assumes are solely used for the conveyance of irrigation water, as these areas may represent GDEs and/or ISWs. These creeks and streams support significant recognized aquatic habitat, wetlands and riparian zones that represent potential environmental beneficial uses and users of groundwater. The minimum thresholds assume that depletions equivalent to historical low groundwater level conditions do not negatively impact ISWs or GDEs, which may be an incorrect assumption.

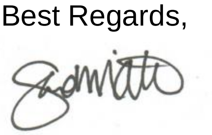
TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for all ISWs – from major rivers to small streams – avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

The Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network is not sufficient to establish a linkage between groundwater extraction and resulting potential impacts to GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of factors. Therefore, the proposed monitoring is not sufficient to detect impacts to GDEs and ISWs.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) install additional monitoring wells and stream gages near potential ISWs and GDEs to further evaluate, monitor, manage and protect areas with ISWs and GDEs; (3) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (4) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,



Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be “significant and unreasonable” are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Eastern San Joaquin Subbasin Groundwater Sustainability Plan

The Eastern San Joaquin Subbasin Groundwater Sustainability Plan (GSP), adopted in December 2019, was reviewed by TNC. Responses to comments are provided in Appendix J (Comments 660–694). The GSA response to our draft comment letter is also provided in Attachment E of this letter. We reviewed the responses to comments and the text of the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the Eastern San Joaquin Groundwater Authority (EJSGWA) during the public comment period, and states whether or not they were addressed in the Final GSP [as green text within brackets]. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 – Notice & Communication (23 CCR §354.10).

- [Section 1.3.1 Beneficial Uses and Users in the Subbasin (pp. 1-42)] [Checklist item 1]
  - *[Section 1.2.1.1 has been updated to include some of this information. Thank you for recognizing some of the protected areas within the Eastern San Joaquin Subbasin that are environmental users of groundwater. The remaining protected areas should also be recognized.]* Caswell Memorial State Park is incorrectly referred to as being located outside the Eastern San Joaquin Subbasin. The following additional protected lands are located near surface waters within the Subbasin that may be interconnected with groundwater, and/or may rely at least partly on groundwater to support vegetation and sensitive natural communities. These protected lands represent potential beneficial users of groundwater: Durham Ferry State Recreational Area, a small portion (approximately 200 acres) of San Joaquin River National Wildlife Refuge, Army Corps Park, Vernalis Riparian Habitat (Public Conservation Lands), Seegers Preserve, Cabral Island Preserve, Machado Preserve, Hansen Preserve, Micke Grove Park and Zoo, Oak Grove Regional Park, Nakagawa Preserve, El Rio Farms Preserve, Lodi Lake Nature Area, Woodbridge Regional Park, Woodbridge Ecological Preserve, White Slough WA, Nuss Farms, Beck Preserve, Hilder Preserve, Staten Island Ranch, Burchel Preserve, and Ishizuka Preserve. The authors referred to the San Joaquin County General Plan documents, including background reports, for information regarding these important resources. These potential beneficial groundwater users should be described in the text on pp. 1-18 and shown in Figure 1-11. **Please include a description recognizing all of the**

protected areas in the Subbasin and their beneficial groundwater uses.

  - *[The GSA responded, "Comment noted" and indicated that this information is beyond the scope of the GSP and can be considered in future updates. No text changes were made. Managed wetlands may be partially dependent on groundwater; therefore, removal of these GDEs from consideration is not adequately justified or scientifically credible.]* Section 2.2.8 includes a geospatial analysis that removes managed wetlands from consideration as GDEs. **The managed wetlands in the Subbasin should be identified in this section.**

Checklist Item 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8).

- *[The GSA's response stated that the comment goes above and beyond the requirements of SGMA and can be evaluated in future iterations of the GSP. No text changes were made. We appreciate the GSA's willingness to further describe GDEs and ISWs and associated monitoring and management programs in future GSPs; however, it should be noted that until these resources and programs are recognized, adequate coordination of GSP implementation with environmental stakeholders cannot be assured.]* [Section 1.2.1 Description of Plan Area (1-10 to 1-23)] Critical habitat is known to exist for protected aquatic species, such as California Tiger Salamander, Steelhead, Delta Smelt, Giant Gartersnake and California Red-Legged Frog in and around the Subbasin (https://fws.maps.arcgis.com/home/webmap/viewer.html?webmap=9d8de5e265ad4fe09893cf75b8dbfb77). There are likely ongoing monitoring programs associated with critical habitat areas and the protected lands. **Please include a description of these habitat areas, and associated programs and requirements pertinent to ISWs, GDEs and wetlands. Identify areas where critical habitat exists and overlaps with ISWs and GDEs.**
- [Section 1.2.2 Water Resources Monitoring and Management Programs (pp. 1-23 to 1-35)] Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *and related surface conditions* (emphasis added). In order for this section to provide the appropriate context and help assure integration of GSP implementation with other ongoing regulatory programs, this section should describe the following:
  - *[The GSA's response noted that the GSP monitoring network meets the requirements of SGMA. Please see the prior comment.]* Monitoring activities and responsibilities by State, Federal and local agencies and jurisdictions related to aquatic resources and GDEs that could be affected by groundwater withdrawals should be discussed. Section 1.2.2.6 states that there are no agencies that do monitoring specific to surface-groundwater interconnection. While this may be technically correct insofar as it relates to hydrogeologic monitoring, it ignores ongoing monitoring programs related to the state of aquatic resources and GDEs that could be affected by groundwater withdrawals, and that are a direct indicator of potential undesirable results. For example, there are likely ongoing monitoring programs associated with

the protected lands listed in our comments to Section 1.3.1, and other open space or preserve areas that may be monitored by public, private or nonprofit entities. **A discussion of monitoring programs related to GDEs and ISWs should be included.**

  - *[Section 4.7 Data Gaps was updated to specifically include GDEs and ISWs. Many of the proposed monitoring wells are near streams and will be used to monitor and further analyze ISWs. Thank you for acknowledging the importance of incorporating GDEs and ISWs in the Data Gap section of the GSP and in proposed future monitoring.]* The lack of existing hydrologic monitoring of surface-groundwater interconnection is a significant data gap as it relates to classification and management of GDEs and should be identified as such and further discussed and addressed in the appropriate subsequent sections of the GSP.
  - *[Section 4.7 was updated to include a discussion of monitoring requirements for ISWs. Thank you for recognizing the importance of monitoring ISWs.]* Monitoring activities and responsibilities related to instream flow and water quality requirements under applicable Federal Energy Regulatory Commission licenses, Biological Opinions and other regulations or programs are relevant and should be identified. **Please include a discussion of water flow and quality monitoring requirements pertinent to ISWs.**

- [Section 1.2.3 Land Use Elements or Topic Categories of Applicable General Plans (pp. 1-35 to 1-40 and Appendix 1-E)]
  - *[The GSA's response stated that there will be additional coordination and refinement of GDE data gap areas as the GSP is refined. No changes to text made. Recognition of General Plan goals and policies in the GSP would help assure that GSP implementation is integrated with General Plan implementation and updates.]* This section should include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals, rather than being limited to goals and policies directly related to groundwater resources alone. Section 1.3.1 correctly identifies environmental uses of groundwater as including "…species and habitat reliant on instream flows, as well as wetlands and GDEs," and yet Section 1.2.3 and Appendix 1-E do not identify any General Plan policies related to these resources. **Section 1.2.3 should identify if there are any Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE and/or ISW habitats. Appendix 1-E should identify General Plan policies related to wetlands, riparian habitat, streams, aquatic habitat, and related threatened and endangered species. Section 1.2.3.2 should include a discussion of the relationship of GSP implementation to General Plan goals and policies related to GDEs and aquatic habitat; and also address how GSP implementation will coordinate with the goals of any HCPs or NCCPs.**

- [Section 1.2.3.4 Well Permitting (pp. 1-38 to 1-40)] **This section should include a discussion of the following:**
    - *[Section 1.2.3.4 has been updated to include Sacramento County well permitting requirements and additional information regarding notice of permit applications and well spacing requirements under Water Code (§ 10726.4(b)). Thank you for recognizing the importance of future well permitting and withdrawals on GDEs.].* Future well permitting must be coordinated with the GSP to assure achievement of the Plan's sustainability goals.
    - *[The GSA did not address this comment. No text changes were made.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). The need for well permitting programs to comply with this requirement should be stated.
    - *[Section 1.2.3.4.3 has been updated to include language on procedures for applicants who are not exempt from the Stanislaus County Groundwater Ordinance. Thank you for protecting GDEs from undesirable results.]* Section 2.3.3.3 discusses potential exemptions from the Stanislaus County Groundwater Ordinance but does not mention the fact that applicants who are not exempt are required to provide substantial evidence that their proposed extraction will not result in undesirable results, including significant and unreasonable impacts to GDEs and surface waters.

Checklist Items 6 and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

- *[The GSA's response stated that the level of detail in the GSP is appropriate. No text changes were made.]* [Section 2.1.7 Geologic Cross Sections (pp. 2-35 to 2-37)] **Please clearly state whether localized perched aquifers are present in the basin. Include example near-surface cross section details that depict the conceptual understanding of shallow groundwater and stream interactions at different locations, including perched and regional aquifers**.
- *[The GSA's response stated, "Comment noted for follow up in next version of GSP." No text changes were made.]* [Section 2.1.8.2 Definable Bottom of the Basin (p. 2-42)] The Bottom of the Basin Boundary was defined by the base of freshwater, which was mapped 45 years ago and pumping since then has very likely resulted in shift in the isohaline contouring in the basin. Defining the bottom of the Subbasin based on geochemical properties is a suitable approach for defining the base of freshwater, however, as noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** This will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption of SGMA due to their well residing outside the vertical extent of the basin boundary. Also, pumping saline groundwater and desalinating it will become increasingly economical under SGMA due to pumping restrictions in the basin.

- [Section 2.1.10 HCM Data Gaps (pp. 2-59 and 2-60)] The Hydrologic Conceptual Model identified several data gaps including the following for groundwater level data: *[The GSA's response was "Comment noted." Section 4.7 Data Gaps was updated to include further refinement of NCCAG areas removed through the GDE analysis. We appreciate acknowledgement of the importance of identifying and refining GDEs and understanding their characteristics.]*
    - Depth- or zone-specific water levels to assess vertical interconnection, including zones within the Principal Aquifer. **Nested monitoring wells would be helpful near surface water to show how pumping is impacting surface water flows and GDEs.**
    - Additional shallow groundwater data near surface waters and NCCAGs.
    - Additional groundwater level data in the east and northwest areas of the Subbasin.
    - Additional groundwater level data near the Mokelumne River to improve quantification and understanding of subsurface flows.

  Of these, the second data gap is the information that is most critical to identifying GDEs or potential GDEs and understanding their characteristics.

Checklist Items 8, 9 and 10 – Interconnected Surface Waters (23 CCR §354.16)

- *[The GSA's response refers to Master Response 2 – ISW, which addresses the comment. No changes to text were made.]* [Section 2.1.4.2 Major Hydraulic Features (pp. 2-9 to 2-14)] This section should discuss (or reference the sections discussing) the following:
    - Specific ISWs, including the extent of both gaining and losing reaches.
    - In-stream flow requirements in each of the interconnected rivers/streams including the amount, time of year when the flow minimum is specified, the duration, the freshwater fish species for which it applies, associated permits that set forth the requirements, and the regulating agency setting forth the compliance requirements.
    - Areas of critical habitat that exist within rivers and streams.
- *[Table 2-2 was updated by removing the statement in the comment.]* [Section 2.1.5 Geologic Formations and Stratigraphy (pp. 2-23 to 2-27)] Table 2-2 states that Holocene Stream Channel Deposits are generally not saturated except by the San Joaquin River. Based on the available data, it would be expected that the stream channel deposits associated with the other ISWs in the Subbasin would be saturated near those streams and rivers.
- *[The GSA's response refers to Master Response 2 – ISW. Section 2.1.9.2.2 was updated to refer readers to Section 2.2.6 for a discussion of historical groundwater-surface water interaction. Thank you for acknowledging the importance of historical groundwater-surface water interactions.]* [Section 2.1.9.2.2 Regional Historic Groundwater Flow and Surface Water Interaction (p. 2-52)] This section focuses on groundwater flow direction and defers further discussion of groundwater conditions to Section 2.2, which does not provide information on historical groundwater-surface water interaction. **This section should include a discussion of historic groundwater-surface water interaction.**

- Section 2.2.6 Interconnected Surface Water Systems (pp. 2-104 to 2-105)]
  - *[The GSA's response refers to Master Response 2 – ISW. Section 2.2.6 was updated to clarify that the ESJWRM historical calibration model results represent the best available information related to interconnectivity between surface water and groundwater, and to describe gaining and losing streams. The comment was incompletely addressed.]* The determination as to whether or not a stream reach is interconnected or disconnected was made based on whether modeling conducted for the GSP indicated that it is interconnected more than 25 percent of the time. Even if the stream is only connected 25% of the time, it is still connected, and that short period of connectivity may be during critical times for select species or provide a cooling or biogeochemical effect during a critical period. **Please describe the technical basis for selecting a 25 percent interconnection threshold, and how it will adequately protect the environmental beneficial uses of surface water in potentially interconnected surface waters from significant and unreasonable impacts related to groundwater extraction.**
  - *[The GSA's response refers to Master Response 2 – ISW, which addresses the comment. No changes to text were made. Data gaps related to ISWs have been updated in Section 4.7.]* Shallow groundwater monitoring data near surface waters and NCCAGs are identified as a data gap in Section 2.1.10, and the use of the Eastern San Joaquin Water Resources Model (ESJWRM) to determine the percentage of time that stream reaches are groundwater connected entails inherent uncertainty. The potential presence of shallow or perched aquifers near the rivers is not assessed or discussed in the GSP. Groundwater modeling conducted by the United States Geological Survey (USGS), DWR and others (e.g., JJ&A, 2018) has considered some river reaches shown as disconnected in Figure 2-66 (p. 2-105) to be groundwater-connected. No data or discussion is presented regarding the potential groundwater connection of other streams associated with significant wetland and riparian resources, including Pixley Slough, Mormon Slough, Littlejohns Creek, Bear Creek, Potter Creek, Duck Creek and Lone Tree Creek. As such, there is considerable uncertainty regarding the designation of interconnected and disconnected surface water resources in Figure 2-66. **The uncertainty regarding the groundwater interconnection of streams in the Subbasin should be identified as a data gap.**

Checklist Items 11 through 20 – Groundwater Dependent Ecosystems (23 CCR §354.16)

- *[Section 2.2.7 has been updated to state that SGMA requires the identification of GDEs and their inclusion as a beneficial user of water to be considered when developing sustainable management criteria. Thank you for including GDEs as a beneficial user of groundwater to be considered when developing sustainable management criteria.]* [Section 2.2.7 Groundwater-Dependent Ecosystems (p. 2-108)] This section includes the incorrect statement that SGMA does not require sustainable management criteria to be established for the management of GDEs. Section 1.3.1 of the GSP states that beneficial users of groundwater and ISWs include "environmental users of groundwater, including species and habitat reliant on instream flows, as well as wetlands and GDEs." Undesirable results under SGMA include chronic lowering of groundwater levels resulting in significant and unreasonable depletion of supply for beneficial groundwater users, *including* GDEs. Undesirable results also include depletion of ISWs resulting in significant and unreasonable adverse impacts on beneficial users of surface water, including wetlands and GDEs. **The incorrect statement that SGMA does not require the establishment of sustainable management criteria for GDEs should be removed.**

- *[The GSA's response refers to Master Response 1 – GDEs. Section 2.2.8 has been updated to better articulate the methodology used and describe the data gaps within the NCCAG dataset. Section 2.2.8 now refers to Section 4.7.4 for information regarding plans to fill GDE-related data gaps. We appreciate the efforts to reclassify GDEs and potential GDEs and the plans to identify existing GDEs that may have been incorrectly eliminated through the screening process as part of future updates to the GSP. We maintain that potential GDEs should be managed as beneficial users of groundwater under the current GSP until data gaps are reconciled and sufficient evidence exists to the contrary.]* [Section 2.2.8 Methodology for GDE Identification (pp. 2-108 to 2-114)] The GSP relies on the NCCAG database developed by TNC for the DWR to identify potential GDEs, and then provides a framework for removing most of these areas from further consideration. **It appears that the preliminary desktop analysis documented in the draft GSP resulted an excessive elimination of the NC dataset polygons mapped in the Eastern San Joaquin Subbasin.** In particular, the methods used to confirm whether or not polygons in the NC Dataset are connected to groundwater in the Eastern San Joaquin Subbasin are highly flawed. We have the following comments on the proposed approach:
    - The GSP takes the approach of removing NCCAGs with "access to alternate water supplies" from consideration as GDEs, and states that in order to be considered GDEs, "there must not be alternate water supplies". Alternate water supplies are assumed to include potential sources of surface water including managed wetlands, irrigated agricultural fields, perennial surface water sources, and other unspecified sources determined by stakeholders on a case-specific basis. This approach is inappropriate and deficient for several important reasons:
        - There is no hydrologic analysis or empirical data provided as a basis for the proposed buffer zones. The hydrologic connectivity between a GDE and a nearby alternative water source is highly dependent on local conditions and can vary seasonally and by year type. In the case of managed wetlands, no consideration is given to the nature of the wetland and surrounding area, the source and frequency of inundation, the soil types, and other features that would be needed to understand the hydrologic connectivity between the wetland and the surrounding area, or even whether the wetland itself it groundwater dependent for a portion of the year. Similarly, no information is given to the topography and hydrology surrounding irrigated agricultural fields, the soil types involved, irrigation practices, whether irrigation is likely to

be curtailed during dry years or during certain crop rotations, and other relevant factors. The hydrologic connectivity of perennial surface water sources cannot be assessed without specific knowledge of the water source, topography and soil conditions. In summary, the adequacy of generic buffer zones to assure GDE access to surface water is unsubstantiated.

  - No information is provided regarding the species residing in the GDEs, their sensitivity to groundwater level declines, or the extent of their reliance on groundwater vs. the proposed "alternate water supplies."
  - There is no evidence of consultation with the regulatory agencies responsible for the protection and management of these resources in the establishment of the proposed framework. It does not appear that any habitat assessments have been conducted.
  - Ecosystems often rely both on groundwater and surface water to meet their water needs (see Best Management Practice #3 in Attachment C of this letter). The availability of "alternate water supplies" to provide some portion of a GDE's water demand does not mean all of its water needs can be met through alternate supplies (i.e., without reliance on groundwater).
  - Groundwater pumping depletes ISWs under both gaining or losing conditions, and GDEs may rely on the interactions of surface water to meet their water requirements.

Simply put, the approach proposes to manage GDEs without consideration to understanding the nature and needs of the resource being managed. A strictly binary approach, designating all NCCAGs as either 100 percent reliant on groundwater or 100 percent reliant on alternate water supplies is inconsistent with the available science and is not supportable. **A scientific rationale for removing areas with access to assumed alternate water sources has not been provided. The deleted potential GDEs should be retained in the GSP and managed as potential GDEs. If further study and consultation with the appropriate regulatory agencies indicates that some areas would not be affected by groundwater withdrawals, consideration could be given to removing them at that time.**

- We have the following additional comments regarding the potential use of buffer zones to exclude NC-Dataset polygons from further consideration as GDEs:
  - **In the case of managed wetlands, the water sources used by the managed wetlands, the type of managed wetlands, the relationship of the wetlands to groundwater, and the wetland manager should be specified. In addition, these managed wetlands should be identified in Section 1.3.1.**
  - Please refer to Attachment C of this letter for best practices in using groundwater data to verify whether NCCAGs are GDEs. The GSP identifies monitoring data for shallow groundwater near ISWs as a data gap. **Please discuss what temporal and spatial data were**

used to identify "shallow groundwater," and identify any data gaps.

- A scientifically defensible rationale and data for applying the proposed buffer zones used to remove NCCAGs areas proximal to alternate water sources from consideration as GDEs has not been provided. In the absence of specific information regarding groundwater levels near these features, which is identified as a data gap in the GSP, it is possible that they are connected to a shallow groundwater table, at least seasonally. This is true of both gaining and losing reaches. Such a connection means they meet the definition of a GDE, regardless of whether the groundwater is replenished by a surface water source (see Best Management Practice #3 in Attachment C of this letter). In addition, the extent of groundwater reliance, and the ability of species to adapt to seasonal and long-term changes in hydrologic conditions, varies from species to species. We acknowledge that proximity to surface water sources and establishment of buffer zones may be an important consideration in GDE management; however, groundwater extraction can still result in drawdown near these areas, especially at the outer fringes of GDEs that are more vulnerable to drawdown. **Buffer zones, if used, must be supported by actual hydrologic and habitat assessment data. If such data and assessments are not available, the areas should not be deleted from consideration and management as GDEs. The need for supporting studies to validate the approach may be identified as a data gap and undertaken in the future.**
- The "stakeholder feedback" mechanism for removal of NCCAGs from consideration as GDEs is not explained or documented in the GSP. **Please provide details that support removing potential GDEs based on stakeholder feedback. Stakeholder feedback, in the absence of scientifically supportable data and/or agency consultation, may be insufficient to exclude areas from consideration as GDEs.**

- We have the following comments about the proposed use of a 30-foot depth to water criterion to exclude NC-Dataset polygons from further consideration as GDEs:
  - SGMA defines GDEs as "ecological communities and species that depend on *groundwater emerging from aquifers or on groundwater occurring near the ground surface*". **We recommend that depth to groundwater contour maps are used, where they can be reliably substantiated, to verify whether a connection to groundwater exists for polygons in the NC Dataset. This is preferable to relying on inferences based on the presence of surface water features in the Basin. However, it is important to note that where depth to water is uncertain in proximity to streams, a depth to water criterion for assessing which polygons are GDEs**

is inappropriate. Please refer to Appendix C of this letter for best practices for using groundwater data to verify a connection to groundwater.

- **Please provide more details on how depth to groundwater contour maps were developed:**
  - Are the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons to reflect local conditions relevant to ecosystems?
  - Are the wells used for interpolating depth to groundwater screened within the surficial unconfined aquifer and capable of measuring the true water table?
  - Is depth to groundwater contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape? This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[2] to estimate depth-to-groundwater contours across the landscape. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to contour depth to groundwater.
- The 30-foot depth to water criterion used to exclude riparian areas near streams east of the San Joaquin River from further consideration as GDEs is very broadly applied and poorly supported. Based on our understanding of the regional hydrogeology, we would expect riparian vegetation and wetlands near the major surface drainages to be connected to water tables associated with the regional aquifer system from a point where the streams exit the foothill uplands westward, except in areas of significant, pumping-induced drawdown. Shallow groundwater data near streams are identified as a significant data gap, and the available groundwater level data come from wells screened at a variety of depths. **The application of a 30-foot depth to water criterion is inadequately supported in light of the identified data gaps, and should not be used exclude potential GDEs from further consideration without additional study.**
- While depth to groundwater levels within 30 feet are generally accepted as being a proxy for confirming that polygons in the NC dataset are connected to groundwater, the variable needs of plant species and their dependence on seasonal and inter-annual

[2] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

groundwater level fluctuations should be considered when applying this criterion. The GSP cites a maximum rooting depth of 25 feet for oak trees as a basis for the 30-foot criterion, yet studies have found the roots of oaks can extend deeper than 70 feet to extract water from the capillary fringe immediately above the water table during the summer and fall, and that groundwater reserves provide a buffer to rapid changes in their hydroclimate, as long as groundwater reserves are not depleted by drought or human consumption.[3] **It is highly advised that seasonal and interannual fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time or contoured with too few shallow monitoring wells can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs.** Based on a study we recently submitted to Frontiers in Environmental Science Journal, we've observed riparian forests along the Cosumnes River to experience a range in groundwater levels between 1.5 and 75 feet over seasonal and interannual timescales. Seasonal fluctuations in the regional water table can support perched groundwater near an intermittent river that seasonally runs dry due to large seasonal fluctuations in the regional water table. While perched groundwater itself cannot directly be managed due to its position in the vadose zone, the water table position within the regional aquifer (via pumping rate restrictions, restricted pumping at certain depths, restricted pumping around GDEs, well density rules) and its interactions with surface water (e.g., timing and duration) can be managed to prevent adverse impacts to ecosystems due to changes in groundwater quality and quantity under SGMA.

- Very little description is provided regarding the nature and function of the identified GDEs, their potential sensitivity to groundwater and surface water supply changes, their relative habitat value, or the current and historical groundwater conditions and variability near the GDEs. Given that monitoring of groundwater levels near ISWs has been identified as a data gap and limited resources are available to expand monitoring efforts in these areas, additional assessment would be helpful to identify and prioritize potential data gaps. **We recommend that a discussion regarding the nature and characteristics of the identified GDEs be included.**

Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)

- [Section 2.3.5 Water Budget Estimates (pp. 2-115 to 2-162)] The following items related to GDEs, wetlands and riparian areas should be clarified or considered:
  - *[The GSA's response indicated that the ESJWRM model does not have the level of detail to determine how much groundwater is consumed by riparian demand. No changes to GSP text made.]* "Riparian intake from streams" is

[3] *Miller and others. 2009. Groundwater Uptake by Woody Vegetation in a Semi-Arid Oak Savannah. Water Resources Research. Volume 46. November.*

identified as a stream system water budget component and is defined as the portion of riparian evapotranspiration (ET) met by streamflows. **Please include an explanation of the approach to determining the amount of riparian ET demand met by streamflow vs. groundwater evapotranspiration.**

  - *[The GSA's response indicated that groundwater outflow to evapotranspiration is simulated indirectly through stream-aquifer interaction and seepage of pumped groundwater in the ESJWRM model. No changes to text were made.]* Groundwater outflow to ET does not appear to be identified as a groundwater budget component (for example see Figure 2-79, p. 2-132). *[The GSA's response indicated that wetlands, GDEs, riparian vegetation, and native vegetation are included in the water budget as part of "Refuge, Native, and Riparian Evapotranspiration." No changes to text were made.]* In addition, the ET demand of natural vegetation does not appear to be considered in water supply and demand calculations (for example see Table 2-16, p. 2-134). **Since GDEs (including wetlands, riparian vegetation, phreatophytes and other communities) are recognized as beneficial users of groundwater in the Subbasin, it is appropriate to include them in these calculations.**

Checklist Items 23 and 25 – Sustainability Goal (23 CCR §354.24)

- *[The GSA's response indicated that the ESJGWA Board determined that the sustainability goal meets the requirements of SGMA. No changes to text were made.]* [Section 3.1 Sustainability Goal (p. 3-1)] The Sustainability Goal is defined as being "… to maintain an economically-viable groundwater resource for the beneficial use of the people of the Eastern San Joaquin Subbasin … ." **Since GDEs, are recognized as beneficial users of groundwater in the Subbasin, they should be mentioned in the Sustainability Goal.**

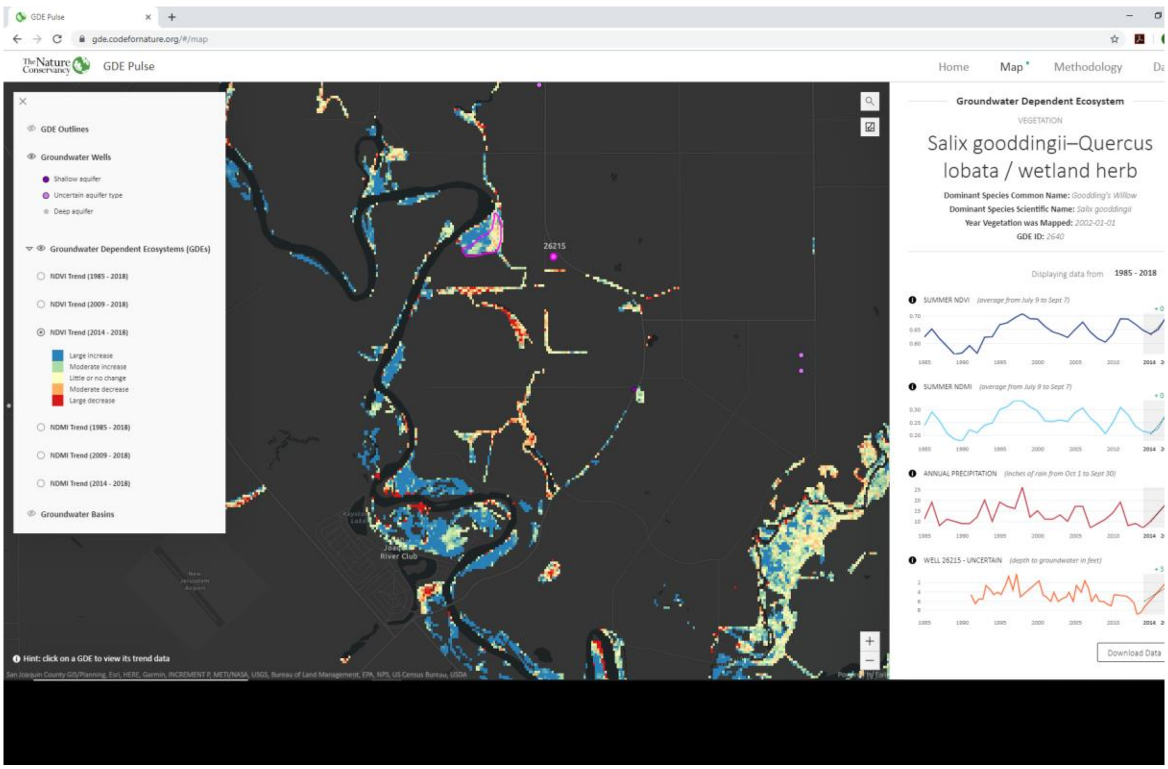
Checklist Item 26 – Measurable Objectives (23 CCR §354.30) and Checklist Items 30 to 33 – Undesirable Results (23 CCR §354.26)

- *[Section 3.2.1.1.1 was updated to include adverse impacts to environmental uses and users, including ISWs and GDEs as undesirable results for chronic lowering of groundwater levels. Thank you for recognizing the importance of environmental uses and users of groundwater.]* [Section 3.2.1.1.1 Description of Undesirable Results (for chronic lowering of groundwater levels (p. 3-3)] This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses that could be adversely affected by chronic groundwater level decline. On page 3-5 in Section 3.2.1.2, impacts to GDEs are correctly identified as an undesirable result potentially associated with chronic groundwater level decline. **Please add "potential adverse impacts to GDEs" to the list of potential undesirable results presented in Section 3.2.1.1.1.**
- *[Section 3.2.3.1.1 was updated to include management of arsenic and nitrate as undesirable results for degraded water quality. Thank you for acknowledging the*

importance of overpumping as a potential source of arsenic and nitrate contamination to drinking water as an undesirable result.] [Section 3.2.3.1.1 Description of Undesirable Results (for degraded water quality (p. 3-11)] This section only describes undesirable results in terms of total dissolved solids concentrations and related impacts. **The section should be modified to state that overpumping and dewatering of aquitards has been identified as a potential source of elevated arsenic concentrations above drinking water standards in San Joaquin Valley aquifers.** The following is a link to a paper by Smith, Knight and Fendorf (2018) titled "Overpumping leads to California groundwater arsenic threat": (https://www.nature.com/articles/s41467-018-04475-3).

- *[The GSA's response stated that ESJGWA recognizes ISWs are a data gap and there is a need for future study and refinement. No text changes were made.]* [Section 3.2.6.1.1 Description of Undesirable Results (for ISWs (p. 3-20)] This section states that undesirable results related to surface water depletion were defined and evaluated only for major streams and rivers including the Calaveras River, Dry Creek, Mokelumne River, San Joaquin River, and Stanislaus River. The section goes on to state that many of the smaller creeks and streams are solely used for the conveyance of irrigation water and these systems have not been considered in the analysis of depletions. Contrary to these statements, surface water resources in these creeks support significant recognized aquatic habitat, wetlands and riparian zones that represent potential environmental beneficial uses and users of groundwater. A number of these streams are associated with designated protected lands. **The analysis for potential depletion of ISWs in Section 3.2.6 should include all beneficial users of surface water that could be affected by groundwater withdrawals, including environmental beneficial users along creeks, even if the creeks are interconnected less than 75% of the time.**
- *[The GSA's response stated that ESJGWA supports the definition of undesirable results and will continue to collect data to inform connectivity conditions in the Subbasin. No text changes were made.]* [Section 3.2.6.1.2 Identification of Undesirable Results (for ISWs (p. 3-21)] The section states that "undesirable results would occur if groundwater extractions depleted interconnected streams and there was not sufficient surface water to supply … fish and wildlife demands." This definition of undesirable results is overly narrow and recognizes only a limited subset of the environmental beneficial users of ISWs. A more complete definition would be that undesirable results would occur if groundwater extraction resulted in a depletion of surface water that caused significant impacts to aquatic species or wildlife, or degradation of GDEs. **Please expand the definition of undesirable results to include all of the environmental beneficial uses and users of ISWs, and expand the analysis in Section 3.2.6, as appropriate.**
- *[The GSA's response stated that language was added to reference beneficial uses and users in the Subbasin; however, no text changes were made.]* [Section 3.2.6.1.4 Potential Effects of Undesirable Results (for ISWs (p. 3-21)] The potential effects of undesirable results on environmental beneficial users are not described. **Please expand the section to describe the potential effects of undesirable results on all beneficial uses and users of ISWs, including environmental uses and users.**

- *[The GSA's response stated that ESJGWA would evaluate using the GDE Pulse Tool and other tools to monitor GDEs. No text changes were made.]* The GDE Pulse web application developed by The Nature Conservancy provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within the Subbasin. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture in the western portion of the Subbasin. An example screen shot from the GDE Pulse tool is presented below. **Please review these spatial patterns and, where possible, correlate them with water level trends. Any indications of adverse trends and any data gaps should be identified.**



-

Checklist Items 27 to 29 – Minimum Thresholds (23 CCR §354.28).

- *[The GSA's response refers to Master Response 2 – ISW, which addresses the comment. No text changes were made.]* [Section 3.2.6.2 Minimum Thresholds (for ISWs (pp. 3-21 and 3-22)] The GSP proposes to use the Minimum Thresholds and Measurable Objectives associated with Chronic Decline in Groundwater Levels as a proxy for management of depletion of ISWs, and concludes that these criteria will be protective of the depletion of ISWs and prevent significant and unreasonable impacts to beneficial surface water uses and users. This conclusion is not adequately supported by data and/or consultation with the agencies that are responsible for the regulation of GDE habitats. We have the following comments:
    - The section states that current or historical issues associated with depletion of ISWs were not indicated to be significant and unreasonable based on

discussions at GWA Board, Advisory Committee, and Workgroup meetings and through input from GSA staff, and that it was therefore assumed that historical conditions are protective of beneficial uses. It does not appear that any consultation occurred with the Federal, State and local agencies responsible for management and regulation of environmental beneficial uses of ISWs, or with the private parties, agencies and NGOs involved in managing the protected lands listed in our response to Section 1.3.1. In addition, no reference is made to the review of supporting documents for General Plan Conservation or Land Use Elements, or to the review of environmental management studies and documents such as Biological Assessments, Biological Opinions, HCPs or other studies regarding the current and historical conditions of the beneficial uses being evaluated. **Please provide a more thorough explanation of the basis for the assumption that current and historical groundwater level conditions are protective of beneficial uses related to ISWs. Data gaps should be acknowledged.**

- The GDE Pulse web application developed by The Nature Conservancy provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within the Subbasin. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture in the western portion of the Subbasin. **Please review these spatial patterns and, where possible, correlate them with water level trends. Any indications of adverse trends and any data gaps should be identified.**
- The section discusses future use scenarios, associated groundwater level declines and ISW depletions on a broad level. The potential effects of these declines on environmental beneficial uses, including GDEs, are not discussed. In addition to discussion of potential adverse effects at a general level, a conclusion that significant adverse impacts are unlikely generally requires more site- and resource-specific analysis. **Please include a discussion of the potential for adverse effects of surface water depletions on environmental resources, as well as a reasoned analysis of the likelihood of their occurrence under future scenarios. The lack of site-specific data to draw conclusions about specific environmental beneficial users should be recognized as a data gap.**
- **Please expand the analysis of potential undesirable results to include all environmental beneficial uses and users, including those associated with more local streams and creeks.**
- The statement that an additional depletion of the surface water due to groundwater pumping of 50,000 acre-feet per year is not significant and unreasonable needs to be further analyzed. The conclusion is based on analyzing the estimated depletion as a percentage of total surface water discharge. The significance of such a depletion relative to specific beneficial uses and users will depend on its distribution throughout the surface water system. Even a modest amount of depletion may have a significant local

adverse effect. **The limitations of broad conclusions regarding basin-wide surface water flow depletions should be recognized and any data gaps identified.**

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

- *[The GSA's response refers to Master Response 2 – Interconnected Surface Water, which addresses the comment. No text changes were made.]* [Section 4.1 Monitoring Network for Chronic Groundwater Level Decline (pp. 4-1 to 4-8) and Section 4.6 Monitoring Network for Depletion of Interconnected Surface Water (p. 4-14)] The GSP proposes to use groundwater level monitoring for chronic groundwater level decline as a surrogate for monitoring the depletion of ISWs. We have the following comments.
    - The areas identified as potential GDEs in the GSP are located near the western boundary of the Subbasin. Only one of the representative monitoring wells appears to be located near those areas (Figure 4-1 on p. 4-5). Very few of the remaining monitoring wells are located near potential ISWs and GDEs. **Specific monitoring should be described to further evaluate, monitor, manage and protect areas with ISWs and GDEs.**
    - Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater ***and related surface conditions*** (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of complicated factors, and this relationship is not characterized or discussed. As such, it is not possible to determine whether the proposed monitoring, minimum thresholds and measurable objectives are sufficiently protective to ensure significant and unreasonable impacts to GDEs and ISWs will be prevented. The GDE Pulse interactive mapping application provides an example of a linkage between groundwater level data and GDE health that could be used to incorporate remote sensing into an efficient and incisive monitoring program. **Please provide an explanation how groundwater levels will specifically be used to assess adverse impacts to GDEs and ISWs, and identify any data gaps and how they will be addressed.**
- [Section 4.7 Data Gaps (pp. 4-15 to 4-18)] Twelve new monitoring wells are proposed to measure groundwater levels and quality in critical areas where data are sparse. These include increased coverage near streams, Subbasin boundaries, and in the central area of groundwater depression. We have the following comments.
    - *[The GSA's response stated that the comment was noted for consideration as proposed monitoring well locations are finalized and for future updates to the monitoring network. No text changes were made.]* Locations should be prioritized near high value or sensitive resources that are vulnerable to significant and unreasonable impacts, such as near the protected lands identified in our comments on Section 1.3.1 or the GDEs identified in the

Subbasin. In addition to the major streams and rivers in the subbasin, impacts to smaller creeks and wetland areas should be considered, as these may be the most vulnerable resources. **Please discuss the results of a resource assessment or consultations with resource managers that demonstrates a sufficient number of wells is proposed to address data gaps near GDEs and ISWs, and that they are being sited where they will provide the most benefit. Alternatively, please outline the process by which this will be accomplished.**

  - *[The GSA's response stated that the impact of groundwater level declines to beneficial users as well as ISWs and GDEs will be considered in updates to the GSP and in annual reports. No text changes were made.]* **As discussed in our comments above, please address how the need to link and correlate groundwater level declines to biological responses, and significant and adverse impacts to GDEs and ISWs will be addressed.**
  - *[The GSA's response stated that the comment was noted for consideration as proposed monitoring well locations are finalized and future updates to the network (including installation of stream gages) are considered. No text changes were made.]* Well sites near ISWs should be selected at varying distances from streams and completed as vertically-nested clusters to capture the lateral and vertical gradients between the pumped depths in the aquifer system and the shallow groundwater aquifers that are in communication with ISWs or GDEs. **There is a need to enhance monitoring of stream flow and vertical groundwater gradients by installing more stream gauges and clustered/nested wells near streams, rivers or wetlands.** Ideally, co-locating stream gauges with clustered wells would enhance understanding about where ISWs exist in the basin and whether pumping is causing depletions of surface water or impacts on beneficial users of surface water and groundwater.
  - *[The GSA's response stated that ESJGWA is committed to resolving data gaps and may develop a program to reevaluate and fill data gaps, as discussed in Section 7.6.4. No text changes were made.]* Addressing data gaps is typically iterative and it is not reasonable to expect it will be a one-time process. **Please describe the process by which data gaps will be identified and addressed on an ongoing basis.**

- *[The GSA's response stated that surface water data including streamflow and water quality is already part of the Data Management System (DMS). No text changes were made.]* [Section 5.3 Data Included in the Management System (pp. 5-6 to 5-8)] Table 5.3 indicates that data regarding streamflow and GDEs is not currently included in the proposed Data Management System. Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *and related surface conditions* (emphasis added). You cannot manage what you do not measure. **Please discuss which monitoring data for "related surface conditions" will be gathered and incorporated in the DMS to assess potential significant and unreasonable impacts to environmental beneficial uses and users**.

- *[Section 6.3 was updated and the statement regarding monitoring groundwater though the use of satellite imagery was removed.]* [Section 7.3.1 Monitoring (p. 7-6)] This section lists the key components involved in implementation of the monitoring network. Groundwater levels and monitoring will occur semi-annually, but no other information is given. Section 6.3 states that "additional management activities are discussed in Chapter 7: Plan Implementation", and would include monitoring groundwater use through use of satellite imagery. However, Chapter 7 does not discuss using imagery or any remote sensing, which is a great tool for monitoring ecosystem health of GDEs and ISWs. **Please clarify the potential use of imagery as a monitoring tool, and expand it to monitoring surface indicators of ISW and GDE ecosystem health.**
- *[The GSA's response stated that while there are no specific plans regarding the use of imagery as a monitoring tool, any publicly available tool, including GDE Pulse, will be evaluated for use in the GSP. No text changes were made.]* [Section 7.3.2.2 Basin Conditions (pp. 7-6 and 7-7)] This section describes what current groundwater conditions and monitoring results will be included in the annual monitoring report. **Please specifically address ecosystem health of GDEs and ISWs as a surface indictor to subsurface conditions.** This can be done using GDE Pulse, remote sensing, imagery or other feasible methods.

Checklist Items 50 and 51 – Project and Management Actions (23 CCR §354.44)

- *[The GSA's response refers to Master Response 5 – Projects but the master response does not specifically address this comment. No text changes were made.]* [Section 6.2.1 Project Identification (p. 6-1)] The Subbasin includes many GDEs and ISWs which represent beneficial uses and users of groundwater, and which include potentially sensitive resources and protected lands. Environmental resource protection needs should be considered in establishing project priorities. In addition, consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**
- *[The GSA's response stated that expected project benefits are included in the text in Chapter 6. No text or table changes were made.]* Table 6-1 (pp. 6-2 to 6-7) lists potential projects and the Measurable Objective that is expected to benefit. Only water level benefits are listed, but maintenance or recovery of groundwater levels, or construction of recharge facilities, also will have environmental benefits in many cases. From the table, it is not possible to distinguish the full range of project benefits or how the projects will be prioritized. **It would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.**
- *[The GSA's response stated that project proposed by individual GSAs will be implemented at the GSA level. No text or table changes were made.]* [Sections 6.2.4 Planned Projects and 6.2.5 Potential Projects (pp. 6-8 to 6-33)]
    - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**

- If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting ISWs.**
- Recharge ponds, reservoirs and facilities for managed stormwater recharge can be designed to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such facilities have been incorporated into local HCPs, more fully recognizing the value of the habitat that they provide and the species they support. For projects that will be constructing recharge ponds, **please consider identifying if there will be habitat value incorporated into the design and how the recharge ponds will be managed to benefit environmental users.**
- Specific examples of how project descriptions may be refined to incorporate environmental benefits include the following:
  - Project 21: Winery Recycled Water will recycle winery wastewater and reuse it for irrigation and in-lieu recharge, or the water will be put into ponds. **Please consider identifying what proportion of water will be put into ponds for direct recharge that could also provide a benefit for wildlife and aquatic species.**
  - Project 23: SSJID Stormwater Reuse will capture stormwater for reuse and recharge. Project 18: Farmington Dam Repurpose Project proposes to more than double storage in Farmington Basin for water supply. **Please consider assessing ways in which these projects could also provide enhanced wildlife and aquatic species benefits.**
  - For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

- *[The GSA's response refers to Master Response 5 – Projects but the master response does not specifically address this comment. No text changes were made.]* [Section 6.3 Management Actions (p. 6-37)] This section lists only administrative actions the GSA will undertake to implement the GSP, and does not identify the management actions to be taken if to assure SGMA compliance if monitoring data indicate that measurable objectives or interim milestones are not being achieved. An adaptive management approach, where monitoring data are used to assess results and inform refinement of the management approach is typically specified. **Please identify what management actions will be taken if monitoring data indicate that Measurable Objectives or Interim Milestones are not being achieved, or undesirable results are imminent.**

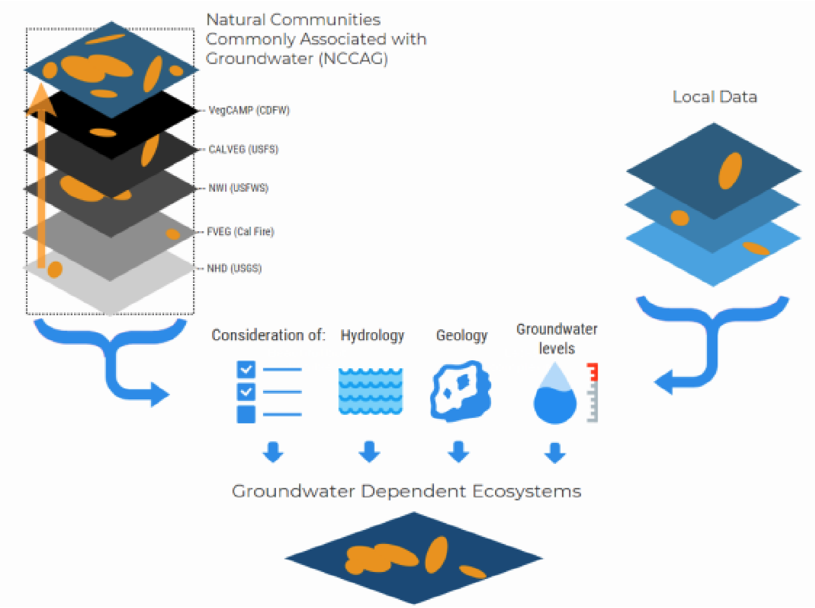
July 2019

IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[4] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[5]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[4] *NC Dataset Online Viewer:* *https://gis.water.ca.gov/app/NCDatasetViewer/*

[5] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[6]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[7] on the Groundwater Resource Hub[8], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

[8] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

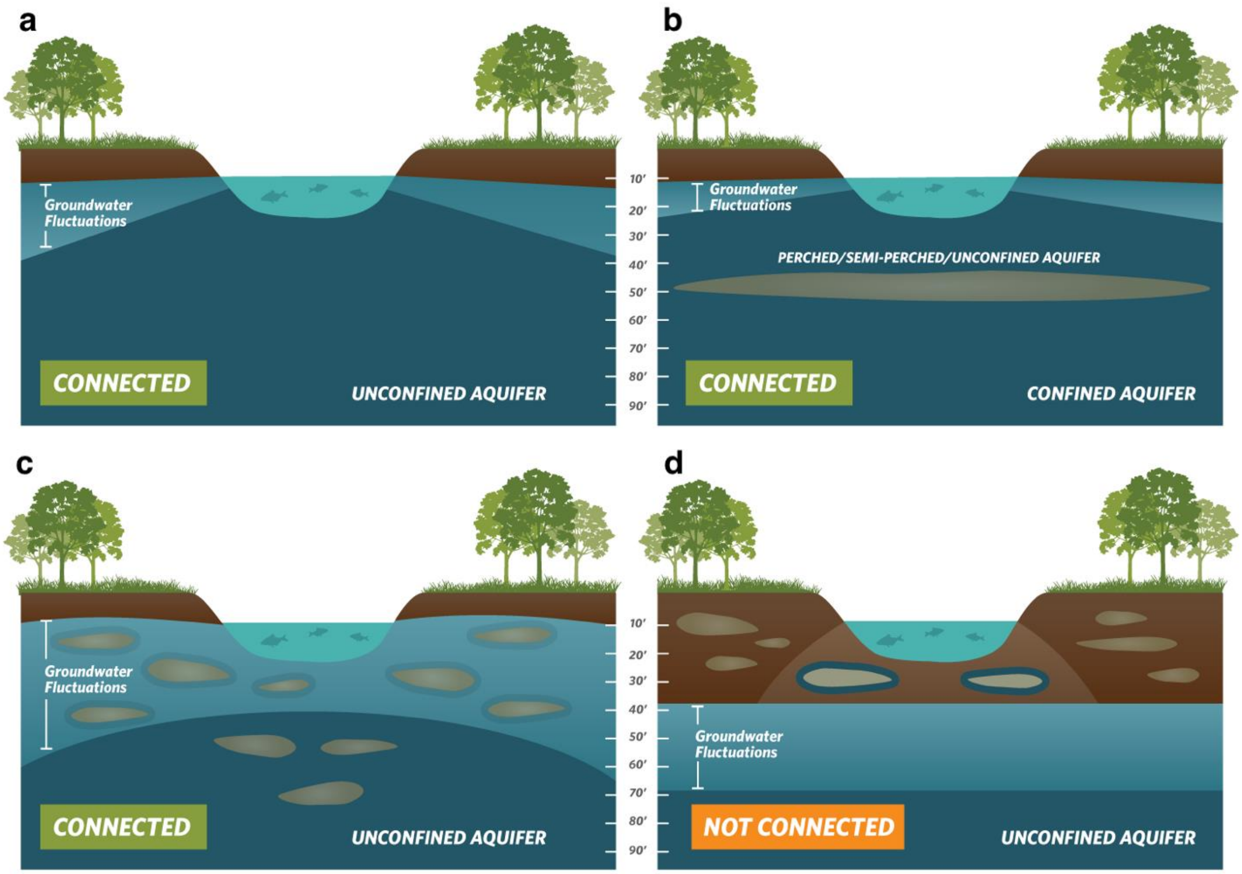

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[9] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[10] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[11] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[12]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

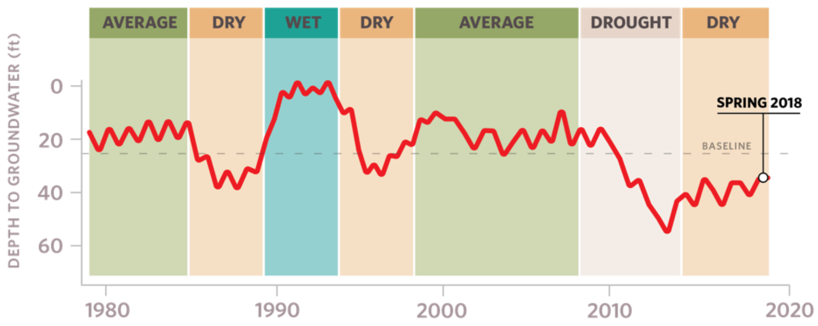

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[9] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[10] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[11] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[12] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[13], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

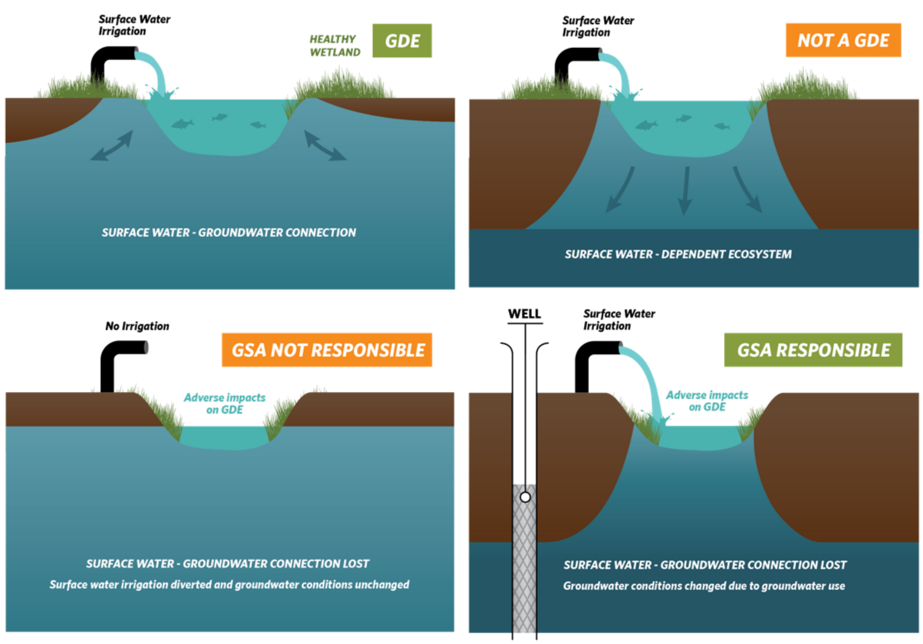

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[13] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

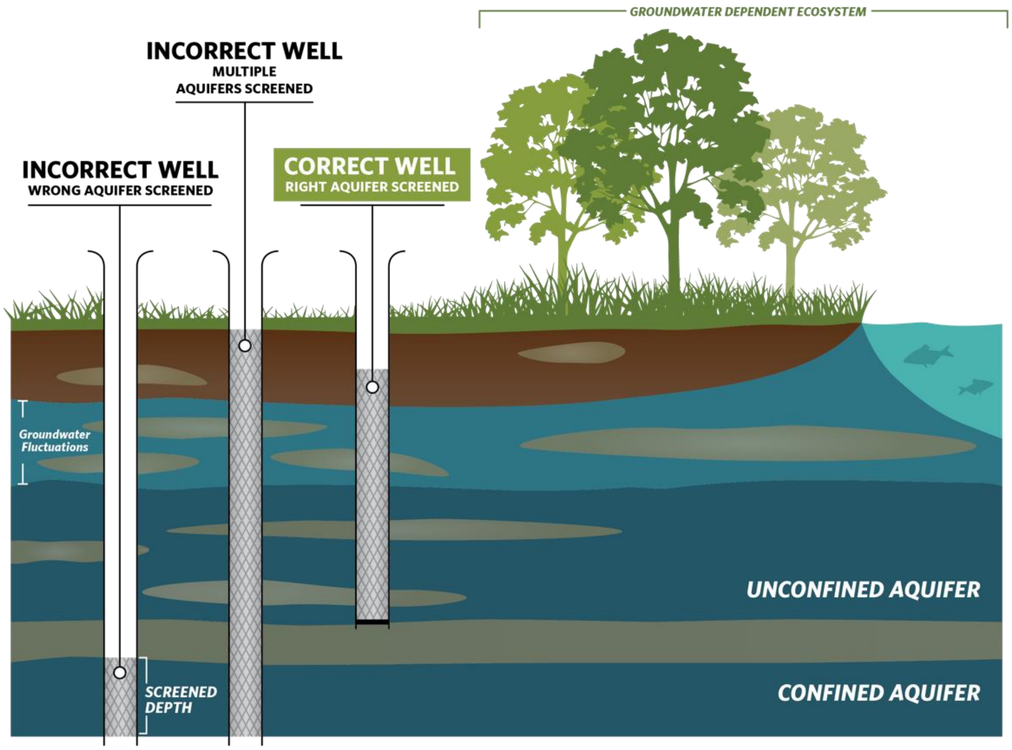

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[14] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

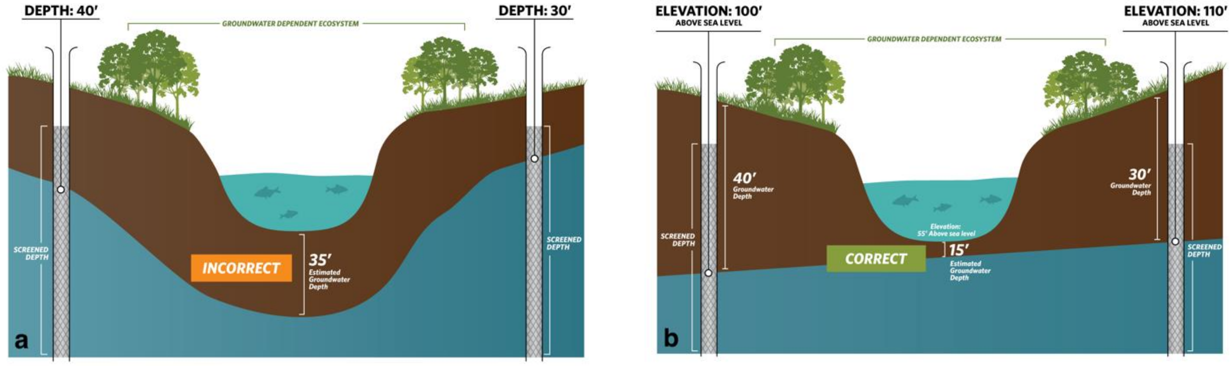

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

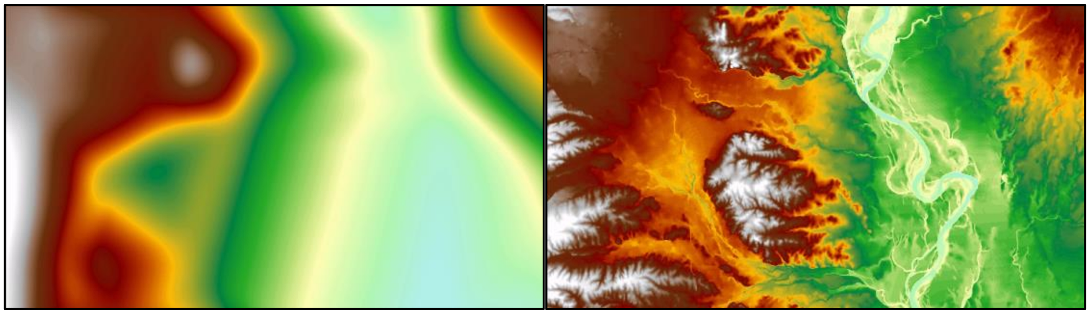

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[14] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

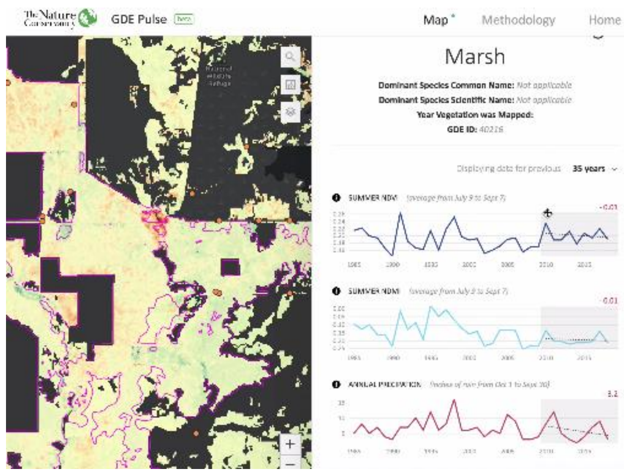
Attachment D

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[15]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[16]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

[15] The Natural Communities Commonly Associated with Groundwater Dataset is hosted on the California Department of Water Resources' website: https://gis.water.ca.gov/app/NCDatasetViewer/#

[16] The PRISM dataset is hosted on Oregon State University's website: http://www.prism.oregonstate.edu/

Attachment E

The GSA Response to TNC Comments on the Draft GSP is attached to the SGMA portal as attachment 2 of 2.

Attachment F

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream

height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[17]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[18]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[19] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Fresno County Management Areas A & B Groundwater Sustainability Plan (GSP), Delta-Mendota Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the County of Fresno Groundwater Sustainability Agency's (GSA's) Fresno County Management Areas A & B (FCMA) Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be incomplete in addressing environmental beneficial uses and users.

While the GSP addressed environmental beneficial users in some respects, our review finds that portions of the GSP should be remedied before being approved. Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some case, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of possible ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been largely ignored in the final plan, as only 7 out of 59 of our comments on the draft GSP were addressed. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience, the GSP did not "adequately respond(d) to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

TNC recommendation: We strongly recommend that the GSA prioritize stakeholder engagement through improvements to the stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters – We are pleased to see that the GSP identified and mapped ISWs. The GSP identifies Fresno Slough, which runs through Management Area B, as the only surface water system connected to groundwater in the FCMA GSP. Seepage rates have been developed and are controlled by water levels in the slough and fine-grained sediments at the bottom of the Mendota Pool. Monitoring of ISWs as described in the Plan utilizes monitoring data from San Luis Delta-Mendota Water Authority (SLDMWA); the stage of the Mendota Pool is monitored daily and water levels in the Mendota Pool have historically been stable. The GSP also identified environmental users of surface water, which is required to assess whether surface water depletions caused by groundwater use are having an adverse impact (23 CCR §354.28(c)(6)).

Map and Assessment of potential ISWs:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the FCMA GSP, 2.9 river miles are interconnected (losing), 9.9 miles may be interconnected but are uncertain based on the groundwater depths. Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

Groundwater Dependent Ecosystems – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 4,640 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

While we were pleased to see that the GSP took some steps to identify and map GDEs, we found that some GDEs were improperly disregarded. We recommend that the GSP remedy the omissions by following our recommendations in Attachment B. The GSP should also revisit all components of the plan where GDEs, as a beneficial user, must be considered, especially in determining undesirable results, minimum thresholds and measurable objectives. Our review found that NC Dataset polygons were improperly removed from the GDE map as follows:

- GDEs were rejected on the basis that groundwater levels were greater than 30 feet at a single point in time. This is approach is inconsistent with the best available science because groundwater levels fluctuate over seasons and between years due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30 feet or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can exclude ecosystems that depend on groundwater.

- Wetland GDEs were removed in areas that were not saturated on a continual basis. This approach is inconsistent with the best available science because GDEs can rely on multiple water sources simultaneously and at different temporal or spatial scales (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow). Justifying the removal based on the level of inundation on aerial photography does not acknowledge multiple sources and different temporal or spatial scales. Using the level of inundation disregards the presence of multiple water sources and could result in Exclusion of wetlands that are groundwater dependent.

TNC recommendation: Request that the GSA use groundwater levels that represent interannual and inter-seasonal variability and utilize additional information provided in our guidance document (Attachment D) to identify and consider GDEs throughout the GSP. Specifically, the GSA should use the Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D. If insufficient data are available to describe groundwater conditions within or near GDEs, those GDEs should be included in the GSP until data gaps are reconciled in the monitoring network.

Water Budget – We would like to commend the FCMA GSP for including the groundwater demands of native vegetation, which includes riparian vegetation, in the historical, current and projected water budgets.

Sustainable Management Criteria – The GSP took steps towards including environmental beneficial users of groundwater and interconnected surface water, however, the Sustainable Management Criteria should be improved to describe potential effects of undesirable results on environmental users of groundwater and confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to beneficial users of surface waters, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)) as these environmental users could be left unprotected by the GSP. Undesirable Result #1, #2, #4, and #5 do not specify impacts to GDEs (Undesirable Result #3 seawater intrusion is not applicable because the subbasin is not a coastal basin). Undesirable Result #6 for depletion of interconnected surface waters states that impacts to GDEs will be further evaluated as more data is collected and data gaps are filled.

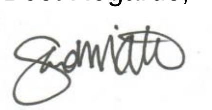
TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

The Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize the interaction of GDEs and other environmental beneficial users with surface water and groundwater. Shallow groundwater data are lacking from the Mendota Wildlife Area of Management Area B south of Whitesbridge Road. Potential GDEs are located along surface water bodies where no shallow groundwater monitoring is proposed, leaving recognized data gaps unfilled. Therefore, GDEs are not being addressed in the monitoring network in the GSP.

TNC recommendation: (1) reconcile data gaps in the monitoring network, particularly in the Mendota Wildlife Area, by evaluating how the gathered data will be used to verify possible GDEs as groundwater dependent; (2) discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions; and (3) add ecological monitoring to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,



Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Fresno County Management Areas A & B Groundwater Sustainability Plan

The Fresno County Management Areas A & B GSP, adopted January 7, 2020 as Resolution No. 20-013, was reviewed by TNC. TNC submitted comments on the Public Draft GSP on December 6, 2019. Responses to comments on the public draft were included as Section 2.5.3 of the GSP. The GSA response to our draft comment letter is provided in Attachment F of this letter. We reviewed the responses to comments and the text of the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the County of Fresno Groundwater Sustainability Agency (GSA) during the public comment period, and states whether or not they were addressed in the Final GSP [as green text in brackets]. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 2.5.1 Description of Beneficial Uses and Users of Groundwater (p.16)]

- *[Thank you for acknowledging beneficial uses and users of groundwater in the GSP. Section 2.5.1 has been updated and identifies beneficial users. Environmental users are listed as the MWA, the Alkali Ecological Reserve, and other GDEs present in the GSP area.]* Beneficial uses are listed as agricultural, domestic and environmental. There are no municipal beneficial users in FCMA. The Fresno County A & B GSP notes that the CDFW owns and operates the MWA. CDFW was contacted regarding the development of the GSP and to obtain access to construct new monitoring wells. There are no further descriptions of the environmental uses until GSP Section 3.1.7, Surface Water Features (p. 31), which describes the Mendota Pool, Fresno Slough, and the canal system near the MWA, but does not discuss the wildlife species that inhabit the areas. **Besides the MWA, please identify whether or not the following beneficial uses and users of groundwater in the Subbasin are present: Protected Lands, including refuges, conservation areas, and recreational areas; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
- *[Section 2.5.1 has been updated and identifies environmental users. Thank you for recognizing environmental users in the GSP.]* The types and locations of environmental uses, species and habitats supported, instream flow requirements, and other designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in FCMA should be specified. **To identify environmental users, please refer to the following:**
    - The NC Dataset (https://gis.water.ca.gov/app/NCDatasetViewer/) which identifies potential presence of groundwater dependent ecosystems.

- The list of freshwater species located in the Delta-Mendota Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.
- CDFW's California Natural Diversity Database (CNDDB) - https://www.wildlife.ca.gov/Data/CNDDB
- USFWS's IPAC report for the FCMA - https://ecos.fws.gov/ipac/

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8).

[Section 2.2 Water Resources Monitoring and Management Programs (p. 12)]

- *[The GSA's response states that "existing streamflow monitoring has not considered the protection of interconnected surface waters" which negatively impacts ISWs because they are not being monitored. As required under SGMA (23 CCR §354.28(c)(6)), identifying environmental users of surface water, gaining and losing reaches, and spatial and temporal variations in streamflow is necessary to assess whether surface water depletions caused by groundwater use are having an adverse impact on ISWs and GDEs, and would serve to protect ISWs and GDEs. No changes to GSP text made.]* The GSP states (p. 12): "The [Mendota Pool Group] MPG Monitoring Program was established in 1999, and over the past two decades of annual reporting has created an extensive record of groundwater, surface water, and geologic data. Some of the MPG monitoring data applicable to the FCMA GSP effort will be used to develop and implement the GSP for FCMA. Existing monitoring locations (e.g., wells, extensometers, surface water sampling locations) will be incorporated, as necessary, into the Subbasin and FCMA monitoring network." **Please explain the relationship of existing stream flow monitoring to the protection of ISWs and GDEs.**

[Section 2.3.1 Fresno County General Plan (p. 12-13)]

- *[The GSA's response states that the general plan is being updated in 2020 and future updates to the GSP will consider the goals of the updated general plan. No changes to the GSP text made.]* The Fresno County General Plan was adopted in 2000, prior to the formation of the GSA. FCMA is designated as "Agricultural" or "Open Space", which refers to the MWA. There are limits to the number of residential units that can be built in those areas. In this section, **please include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**
- *[The GSA's response states that there are no HCPs or NCCPs in the FCMA. No changes to the GSP text made.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify any**

relevant HCPs and NCCPs within the Subbasin, and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.

- *[The GSA's response states that GSP regulations do not require the identification of individual species and that the identification of GDEs accounts for all species that may occupy a GDE. Because critical species and their habitats have not been identified, these aquatic species are not being managed or protected by the GSP. The GSP would benefit from the inclusion of a discussion regarding the management of critical habitat. No changes to the GSP text made.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**

[Section 2.4.4 Well Construction, Well Destruction, Abandonment (p. 13)]

- *[The GSA's response was "Comment noted." No changes to the GSP text made.]* The County of Fresno has the authority to require permits for well abandonment, construction of new wells, reconstruction, repair, and deepening existing wells. Well permitting is currently handled by the Fresno County Environmental Health Department. The DWR well construction/destruction standards are followed (Bulletin 74-81 and 74-90). **Please include a discussion of how future well permitting will be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**
- *[The GSA's response was "Comment noted." No changes to the GSP text made.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF vs. SWRCB and Siskiyou County, No. C083239). **Compliance of well permitting programs with this requirement should be stated in the GSP.**

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 3.1.2 Local Geologic Setting (p. 25-28)]

- *[The GSA's response states that the GSP regulations do not require development of a cross section to depict the interaction of shallow groundwater with surface water features and does not address our comment. The GSP would benefit from the inclusion of a conceptual diagram that show the interaction of shallow groundwater with any potential GDEs and ISWs. No changes to the GSP text made.]* The basin-wide cross sections modified from Miller et al. (1971) (Figures 3-4 through 3-5) are regional, and do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. **Please include an example near-surface cross section that depicts the conceptual understanding of the interaction of shallow groundwater with the Fresno Slough, as well as any potential GDEs and ISWs**.

[2] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

[Section 3.1.6 Definable Bottom of Basin (p. 31)]

- *[The GSA's response states that the base of freshwater is well below the Corcoran Clay; however, there are no known wells in the FCMA screened below the clay, therefore the base of freshwater is based on regional well data and is not well defined. The GSP would benefit from the inclusion of groundwater extraction well depth data for the determination of the basin bottom. No changes to the GSP text made.]* In the FCMA, the base of the usable aquifer corresponds with the base of freshwater, generally defined as groundwater with total dissolved solids (TDS) of 2,000 mg/L (Page, 1973), consistent with other GSAs in the Delta-Mendota Subbasin. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.

[Section 3.1.3 Principal Aquifers and Aquitards (p. 28-30)]

- *[The GSA's response states that that the shallow zone has not been identified as a principal aquifer, but part of the Upper Aquifer which is a principal aquifer; however, no changes to the GSP text were made. The GSP would benefit from a clarification that the Upper Aquifer consists of the upper zone and the shallow zone from DWR Bulletin 118.]* The GSP states (p. 28): "DWR Bulletin 118 defines three water-bearing zones within the Subbasin. These include the lower zone (defined as the Lower Aquifer), which contains confined fresh water in the lower section of the Tulare Formation, an upper zone (defined as the Upper Aquifer) which contains confined, semi-confined, and unconfined water in the upper section of the Tulare Formation and younger deposits, and a Shallow Zone which contains unconfined water within about 25 feet of the land surface (Davis 1959). This GSP defines two principal aquifers. The Lower Aquifer which is defined as the lower zone in Bulletin 118, and the Upper Aquifer which consists of the upper zone." **Please clarify in this section that the Upper Aquifer as referred to in this GSP consists of the upper zone and the shallow zone from DWR Bulletin 118, if that is the intended meaning. This seems to be confirmed in the following Section of the GSP (3.1.3.1 Upper Aquifer) but should be clearly stated in the first paragraph of Section 3.1.3 Principal Aquifers and Aquitards.**

[Section 3.1.7 Surface Water Features (p. 31-32]

- *[Section 3.1.7 has been updated and states that there is one potential wetland along the Fresno Slough and the rest of the wetlands are mapped as riverine. Thank you for recognizing the presence of wetlands along the Fresno Slough.]* The GSP states (p. 32): "There are not any naturally occurring springs, seeps, or wetlands in FCMA or within the model domain." This sentence seems inconsistent with other parts of the GSP, particularly section 3.2.7 Identification of Groundwater Dependent Ecosystems, which refers to wetland GDEs on the banks of the Fresno Slough. **Please revise the text to clarify the presence of wetlands, distinguishing between natural and managed wetlands if necessary.**

Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)

[Section 3.2.6 Interconnected Surface Water Systems (p. 41)]

- *[The GSA's response was "Comment noted." No changes to the GSP text made.]* The GSP confirms that the Fresno Slough is an ISW. The GSP states (p. 41): "Water levels in the Slough are controlled by the SJREC and USBR in coordination with the San Luis Delta-Mendota Water Authority (SLDMWA)." Table 3-2 provides seepage rates from the Fresno Slough to the Upper Aquifer. **Please state whether seepage rates have been quantified by reach or season and present these if known, based on the cited source [LSCE and KDSA (2000)] or other sources.**

Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)

[Section 3.2.7 Identification of Groundwater Dependent Ecosystems (p. 41-43)]

- *[The definition of GDEs in Section 3.2.7 has been updated. Thank you for acknowledging GDEs and including the definition of GDEs from the GSP regulations in the GSP.]* The GSP states (p. 41): "GSP regulation (§ 351 m) defines GDEs as ecological communities of species that depend on groundwater emerging from aquifers or on groundwater occurring within 30 feet of the ground surface." However, the exact text of the regulation is: "Groundwater dependent ecosystem refers to ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface." **Please revise the GSP text to correctly reflect the text of the regulation.**
- *[The GSA's response was "Comment noted." No changes to GSP text made.]* The GSP states (p. 42): "For the vegetation data set, GDEs were first evaluated by using depth to water (DTW) measurements from Spring 2015 from Shallow Zone wells (screened above the A-Clay). Based on a water level threshold of 30 ft below ground surface (ft bgs), areas with water levels greater than 30 ft bgs were removed as containing GDEs, and areas with water levels shallower than the threshold were kept as GDEs." We have the following comments on this methodology:
    - **Please provide more details on how the depth to groundwater contours shown on Figure 3-37 were developed**:
        - Are the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons to reflect local conditions relevant to ecosystems?
        - Is depth to groundwater contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape? This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide much

more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to contour depth to groundwater.

- *[The GSA's response was "Comment noted." No changes to GSP text made.]* Spring 2015 is after the SGMA benchmark date of January 1, 2015. **Please ensure that groundwater condition data prior to the SGMA benchmark date of January 1, 2015 is included in the analysis.**
- *[The GSA's response was "Comment noted." No changes to GSP text made.]* It is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2015) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network**.
- *[The GSA's response states that GSP regulations do not require identification of potential vegetation. TNC's comment concerning the 30-foot depth criteria for removing GDEs was not addressed. GDEs were removed based on groundwater levels that were greater than 30 feet at <u>a single point in time</u>. This approach is technically incorrect because groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. TNC recommends that the GSP use groundwater levels that represent interannual and inter-seasonal variability to identify GDEs in the GSP. No changes to GSP text made.]* **Please provide rationale for the 30-foot criteria cited in the text.** In TNC's GDE Guidance, the depth criteria of 30 feet is presented as a criterion for inclusion, not a standalone criterion for exclusion. In other words, if groundwater is within 30 feet of the ground surface, then a GDE can be identified. If it is not, then further analysis must be conducted (see Appendix III of the GDE Guidance, Worksheet 1, for other indicators of GDEs). **Please indicate what vegetation is present in the possible GDEs. The actual rooting depth of vegetation growing in the area should be a consideration, and this will vary by species dominance and habitats present.** For example, some phreatophytes can

root to 120-feet deep in more arid and drought-stressed environments. Furthermore, rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant. Maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not prefer to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths.

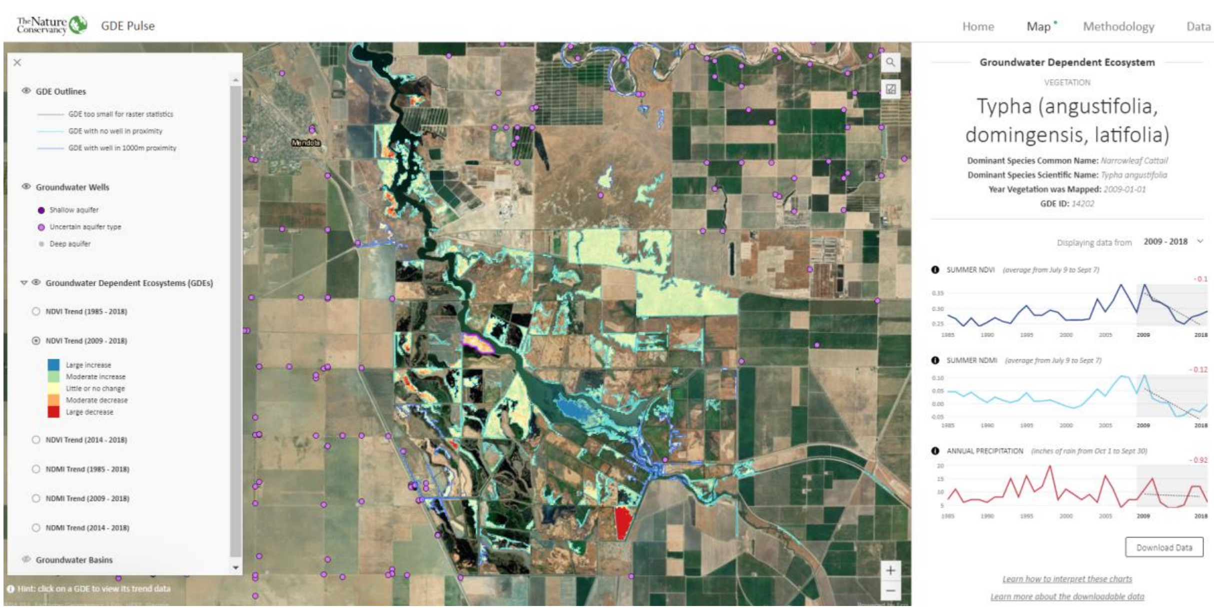
- *[The GSA's response incorrectly assumes that Wetland GDEs cannot exist where the depth to groundwater is greater than 30 feet. The text in Section 3.2.7.1 was revised to state that wetland GDEs along the banks of the Fresno Slough were removed because based on historic imagery they are only saturated during wet years and contain minimal vegetation. The use of aerial imagery to characterize groundwater conditions around Wetland GDEs is not scientifically robust.]* The GSP states (p. 42): "For the wetland's dataset, the areas of the Fresno Slough that were continually saturated based on historic imagery were designated as GDEs. The Fresno Slough runs through the entire FCMA. The banks of the Fresno Slough were classified as GDEi in the wetlands data set. Based on historic imagery these areas are only saturated during wet years such as 2011 and 2017. These areas were removed as GDEs." SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface". GDEs can rely on multiple water sources simultaneously and at different temporal/spatial scales (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow). **Hence, we recommend that depth to groundwater (and not the level of inundation on aerial photography) be used to identify if a connection to groundwater exists. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network.**
- *[Figure 3-37 was updated with separate colors for Vegetation and Wetland GDEs that were kept/removed/added. Thank you for acknowledging the difference between Wetland and Vegetative GDEs, mapping them separately, and providing reasons for each category. We appreciate the County of Fresno's thorough characterization of GDEs. Reasons for those removed/added were provided in the text, however, acreages were not provided. The GSA's response stated that "Acreages of GDEs maintained and removed are not required by regulations." While this is true, the GSP would benefit from providing the acreages kept/removed/added and the reasons for each, which would serve to protect GDEs. The GSA did not submit a GDE shapefile via the SGMA Portal.]* **On Figure 3-37, please provide separate colors for Vegetation and Wetland GDEs removed, as was presented on Figure 2-9, and provide the removal reason. In the text or on the Figure, please cite the acreage of GDEs retained and removed. The basin's GDE shapefile, which is submitted via the SGMA Portal, should include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).**

- *[The text was updated to refer to Table 3-2. The reference to seepage from the* *Mendota Pool* *was not changed to* *Fresno Slough*.*]* The GSP states (p. 43): "There is also significant seepage from the Mendota Pool to the Shallow Zone of the Upper Aquifer which helps maintain GDEs (Table 3-3)." **Please correct the text to refer to *Table 3-2* and seepage from the *Fresno Slough*.**

Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)

[Section 3.2.7 Identification of Groundwater Dependent Ecosystems (p. 41-43)]

- *[The GSA's response states that GSP regulations do not require the identification of individual species. No changes to GSP text made.]* In Section 3.2.7.2, the GSP discusses mapped critical habitat of the endangered Fresno Kangaroo Rat as shown in Figure 3-38. However, this is only a very limited evaluation of ecological conditions and assessment of conservation value of GDEs. **Please provide an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes the vegetation types or habitat types and rank the GDEs as having a high, moderate or low value; and what characterizes the rank.**
- **Please refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI).** Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in FCMA:



[Section 3.2.7.3 Impacts to GDEs (p. 37)]

- *[The GSA's response was "Comment noted." No changes to GSP text made.]* The evaluation of impacts to GDEs is to be performed when defining undesirable results in the SMC section of GSP, not the Basin Setting section. **Please consider moving this discussion and consolidating it with Section 4.4 Undesirable Results**.

Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)

[Section 3.3.6 Quantification of Current, Historic, and Projected Water Budget (p. 44-53)]

- *[The GSA's response addresses the comment, but no change to GSP text made.]* The water budget was calculated with the USGS MODFLOW-NWT model (Niswonger et al., 2011) for an area larger than the boundaries of FCMA, as shown on Figure 3-39. **Please explain how the extended area affects the accuracy of the model projections for the FCMA.**
- *[The GSA's response states that natural vegetation includes riparian vegetation, but no changes to GSP text made.]* Appendix I (p. 19-20) states: "Crop coefficients for different land surface characteristics, including non-irrigated lands such as bare ground, barren/fallow lands and natural vegetation, were calculated based on the UC Davis Basic Irrigation Scheduling (BIS) application developed by Snyder et al. (2000, 2008) at monthly frequency." **Please clarify whether the term "natural vegetation" includes riparian vegetation for evapotranspiration for the historical, current, and future water budgets.**
- *[Table 3-5 (p. 47) has been updated and identifies recharge ponds and canals as other direct recharge. Thank you for providing clarification regarding recharge ponds and canals in the water budget.]* The term "Other Direct Recharge" is not defined, and although it is shown in Current and Historic Groundwater Budget (Table 3-8), it is not included in the Projected Budget (Table 3-9). **Please explain how this term is derived and what it represents.**

Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)

[Section 4.1 Sustainability Goal (p. 57)]

- *[The GSA's response was "Comment noted." No change to GSP text made.]* The GSP states the Sustainability Goal as (p. 57): "FCMA will manage groundwater resources in a manner that results in the absence of undesirable results for the Upper Aquifer by the year 2040." The sustainability goal does not specifically mention beneficial uses or users of groundwater, including environmental users. **Please rephrase the Sustainability Goal to specifically call out beneficial uses and users of groundwater, including environmental users. Please state how the sustainability of environmental uses will be protected. In addition, a statement about any intention to address pre-SGMA impacts should be included.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Section 4.2.1 Measurable Objectives for Chronic Lowering of Water Levels (p. 58)]

- *[The GSA's response addresses the comment, but no changes to GSP text made.]* The description of Measurable Objectives does not explain how GDEs were considered. **Please include GDEs in this section and explain how the Measurable Objectives and Interim Milestones will help achieve the Sustainability Goal as it pertains to the environment.**

[Section 4.2.4 Measurable Objectives for Degraded Water Quality (p. 61)]

- *[The GSA's response does not address the comment, and no changes to GSP text made.]* The description of Measurable Objectives does not consider how water quality needs of GDEs were considered. **Please include a discussion about GDEs and water quality and whether the Measurable Objectives and Interim Milestones will help achieve the Sustainability Goal as it pertains to the environment.**
- *[The GSA's response does not address the comment, and no changes to GSP text made.]* This section describes how for this sustainability indicator, Management Area A and B are designated as separate management areas, based on existing groundwater quality studies and regulatory guidelines. **Please incorporate discussion of the management areas into the explanation of how GDEs will be protected by the SMC for this sustainability indicator.**

[Section 4.2.5 Measurable Objectives for Interconnected Surface Waters (p. 63)]

- *[The GSA's response was "Comment noted." No changes to GSP text made.]* The GSP states (p. 57): "This area has been designated as a management area because it has no control over water levels in the Fresno Slough. FCMA will prevent undesirable results to surrounding areas by managing groundwater elevations to sustainable levels." **Please describe the regulatory requirements that affect surface water deliveries to the Fresno Slough and describe the conditions under which Undesirable Results *could* occur, even if outside of the control of FCMA.**

Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28)

[Section 4.3.1 Minimum Thresholds for Chronic Lowering of Groundwater Levels (p. 65)]

- *[The GSA's response does not address the comment. No changes to GSP text made.]* The discussion of Minimum Thresholds does not consider GDEs. **Please include a discussion of GDEs and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**
- *[The GSA's response does not address the comment because the data gaps section cited does not specifically describe the data gap in shallow groundwater levels in the MWA. No changes to GSP text made.]* The GSP states (p. 66): "For most of the FCMA, there was either no groundwater elevation data present where GDEs are present, primarily the MWA, or groundwater elevations were at a depth that exceeded the 30 ft threshold which was used to identify GDEs," and goes on to state (p. 67): "If water levels are ever to drop to MT levels, which is not projected to occur, further analysis of the vertical gradient in the Shallow Zone of the Upper Aquifer will be necessary to better understand the potential impacts to GDEs."

Please specifically cite the data gap in shallow groundwater levels across FCMA in this section, and state how the data gap will be reconciled or refer to a subsequent section of the document.

[Section 4.3.4 Minimum Thresholds for Groundwater Quality (p. 69)]

- *[The GSA's response does not address the comment. No changes to GSP text made.]* The GSP states (p. 71): "The impact high salinity in groundwater could have on freshwater aquatic plants and animals is not well understood in the San Joaquin Valley (USBR, 2018)." **Please further discuss the possible impacts to environmental users from the Minimum Thresholds for TDS proposed in Table 4-10, in the context of information provided in USBR, 2018 and other sources.**

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 4.4.1.1 Description of Undesirable Results for Groundwater Elevation (p. 75)]

- *[The GSA's response was "Comment noted." No GSP text changes made.]* The GSP states (p. 75): "Undesirable results occur when more than 25% of wells in the Upper Aquifer exceed the established MT value for two consecutive years." The use of 25 percent to define an undesirable result does not allow for the occurrence of low water levels in one area, such as near a GDE, to be an Undesirable Result. Damage to GDEs can occur within a relatively short period of time and can be irreversible, leading to a permanent loss. A percentage violation trigger is therefore an insufficient method to prevent undesirable results to environmental users of groundwater. **Please consider the use of separate management areas for the GDE Units, so that Sustainable Management Criteria protective of GDEs can be established for the GDE Units. Please elaborate on how the exceedance criteria would be applied in a way that is protective of significant and unreasonable harm to GDEs.** A procedure could be included for violation of minimum thresholds that includes early identification of potential GDE impacts and appropriate response actions. This could be accomplished efficiently and cost-effectively using remote sensing tools, such as GDE Pulse.
- *[The GSA's response was "Comment noted." No GSP text changes made.]* **Please provide more specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs.** The definition of 'significant and unreasonable' is a qualitative statement that is used to describe when undesirable results would occur in the basin, such that a minimum threshold can be quantified. Potential effects on all beneficial users of groundwater in the basin need to be taken into consideration. According to the California Constitution Article X, §2, water resources in California must be "put to beneficial use to the fullest extent of which they are capable". **Please identify appropriate biological indicators that can be used to monitor potential impacts to environmental beneficial users due to groundwater conditions. Refer to Appendix E of this letter for an overview of a free, new online tool for monitoring the health of GDEs over time.**

[Section 4.4.1.4 Description of Undesirable Results for Groundwater Quality (p. 75)]

- *[The GSA's response was "Comment noted." No GSP text changes made.]* The GSP states (p. 75): "Undesirable Results occur when more than 25% of wells in MAA or MAB exceed the established MT for two consecutive years." As stated above, the use of 25 percent to define an undesirable result does not allow for the occurrence of low water levels in one area, such as near a GDE, to be an Undesirable Result. Damage to GDEs can occur within a relatively short period of time and can be irreversible, leading to a permanent loss. A percentage violation trigger is therefore an insufficient method to prevent undesirable results to environmental users of groundwater. **Please consider the use of separate management areas for the GDE Units, so that Sustainable Management Criteria protective of GDEs can be established for the GDE Units. Please elaborate on how the exceedance criteria would be applied in a way that is protective of significant and unreasonable harm to GDEs.** A procedure could be included for violation of minimum thresholds that includes early identification of potential GDE impacts and appropriate response actions. This could be accomplished efficiently and cost-effectively using remote sensing tools, such as GDE Pulse.

[Section 4.4.1.5 Description of Undesirable Results for Interconnected Surface Water (p. 76)]

- *[Section 4.4.1.5 was updated and states that the impacts to GDEs due to potential undesirable results will be further evaluated as more data is collected and data gaps are filled. TNC appreciates your willingness to further refine potential undesirable results that may impact GDEs.]* The GSP states (p. 76): "Undesirable results occur when stage values drop below the MT for two consecutive years. Undesirable results for interconnected surface waters will not trigger any management action as FCMA has no control over water levels in the Fresno Slough." The cause-effect relationship between surface water levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of factors, and this relationship is not characterized or discussed. **Please describe what Undesirable Results could be expected when stage values drop below the MT for two consecutive years.**

<u>Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)</u>

[Section 4.5.2 Groundwater Elevation Monitoring Network (p. 79)]

- *[The GSA's response restates a previous sentence from Section 4.5.2 and does not address our comment. The text in Section 4.5.6 (p.80) was revised to state that "the FCMA will work to improve the Interconnected Surface Water Monitoring Network by installing shallow groundwater monitoring wells in the Mendota Wetland Area to be able to better characterize the relationship between GDEs and ISWs in this area."]* **Please incorporate the discussion of data gaps presented in Section 3.1.8 (p. 33) into the Monitoring Network section.** As discussed on page 33, there are no wells in the MWA and the GSA has been unsuccessful in working with CDFW to obtain well construction information on existing wells or to obtain access to construct a new well. This is a data gap for which the GSA states that they will continue to work with DWR, CDFW and private duck clubs to obtain access to construct a new well.

- *[The GSA's response addresses the comment, but no GSP text changes made.]* The five wells that are proposed for monitoring groundwater levels are shown in Figure 4-1. The single well for the Lower Aquifer, USGS 31J6, is located outside of the FCMA. The GSP states that there is no known pumping in the FCMA from the Lower Aquifer, and that the FCMA is not expected to extract groundwater from the Lower Aquifer. Lower Aquifer conditions will be monitored and managed in coordination with other entities that utilize the Lower Aquifer as a source of groundwater. **Please consider the installation of a nested well to study the impact of pumping from the Lower Aquifer in areas adjacent to FCMA to shallow groundwater levels in FCMA. Despite no current pumping from the Lower Aquifer in FCMA, pumping from this aquifer could occur in the future.**
- *[The GSA's response addresses the comment, but no GSP text changes were made. The GSP would benefit from the inclusion of information about installing additional shallow wells and/or staff gauges at related surface water monitoring locations to fill data gaps in the monitoring network, which would serve to protect ISWs and GDEs.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *and related surface conditions* (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The Mendota Pool staff gage will continue to be measured; it is the only monitoring that is planned for the ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of factors, and this relationship is not characterized or discussed. **As such, it is not possible to determine whether the proposed monitoring is sufficiently protective to ensure significant and unreasonable impacts to GDEs and ISWs will be prevented. Please expand the discussion of the monitoring program to discuss how ISWs and GDEs will be protected.**

Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Section 5 Projects and Management Actions to Achieve Sustainability Goal (p. 86)]

- *[The GSA's response was "Comment noted". No GSP text changes made.]* The GSP states that no PMAs (Projects and Management Actions) have been formally developed for FCMA. **If and when future projects are planned, please include environmental benefits and multiple benefits as criteria for assessing project priorities.** Environmental users and uses should be considered in establishing new projects. In addition, consistent with existing grant and funding guidelines for SGMA-related work, consideration may be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities.
- **Please consider adding Management Actions which include education and outreach for protection of GDEs and ISWs.**

Attachment C

Freshwater Species Located in the Delta-Mendota Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Delta-Mendota Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[4] as well as on TNC's science website[5].

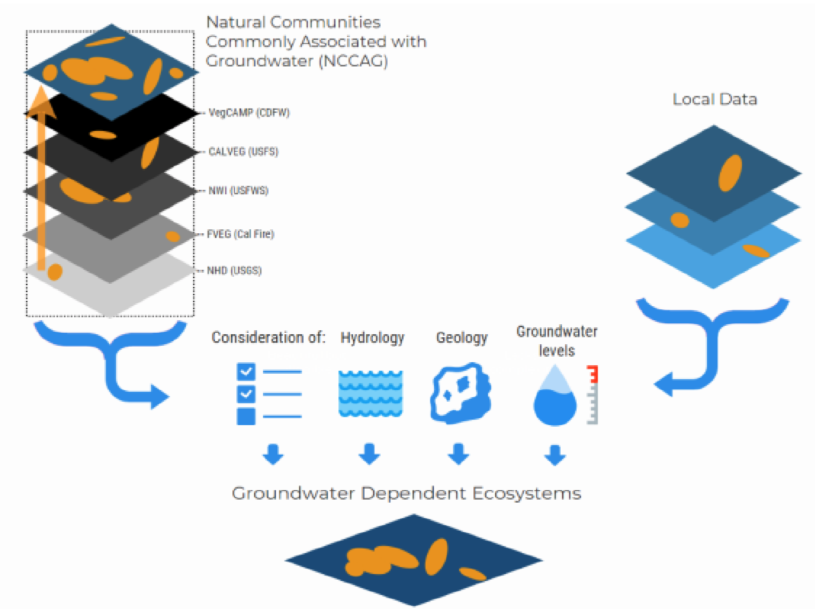
IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[6] *NC Dataset Online Viewer:* *https://gis.water.ca.gov/app/NCDatasetViewer/*
[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

[10] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

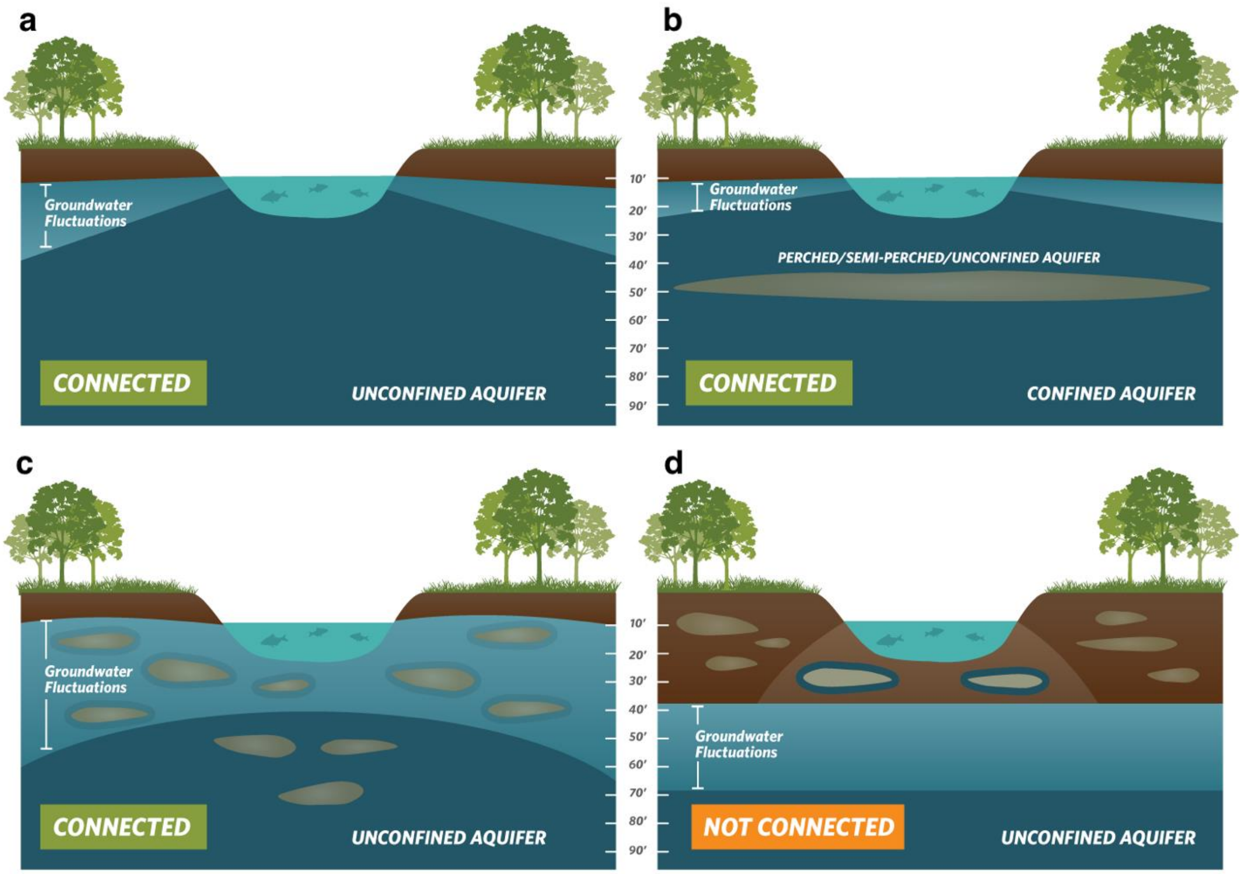

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

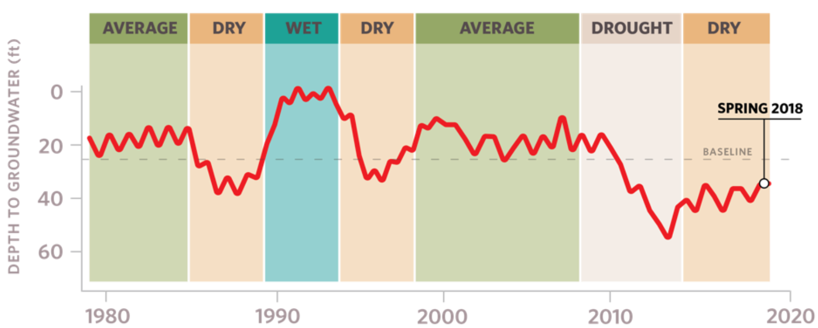

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

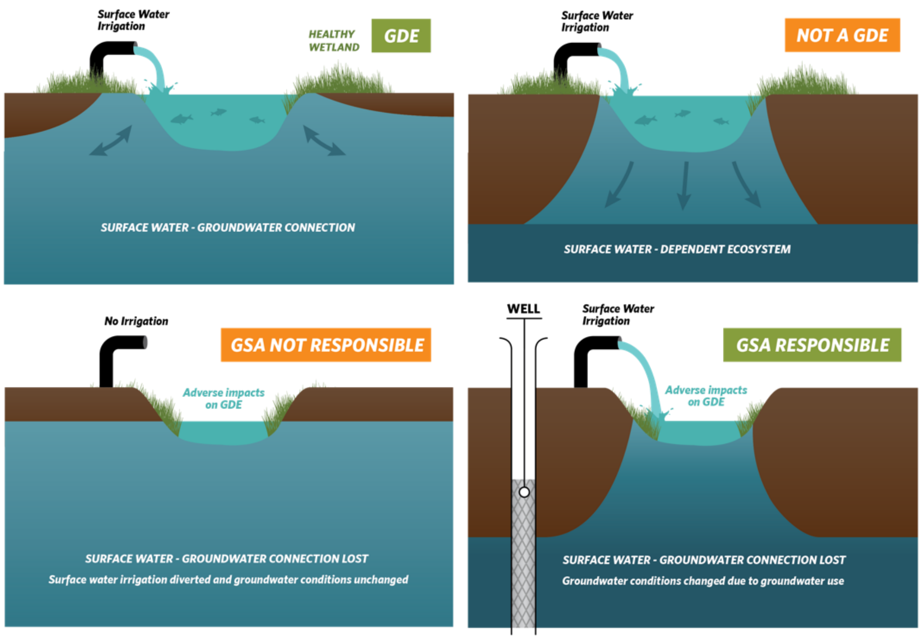

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

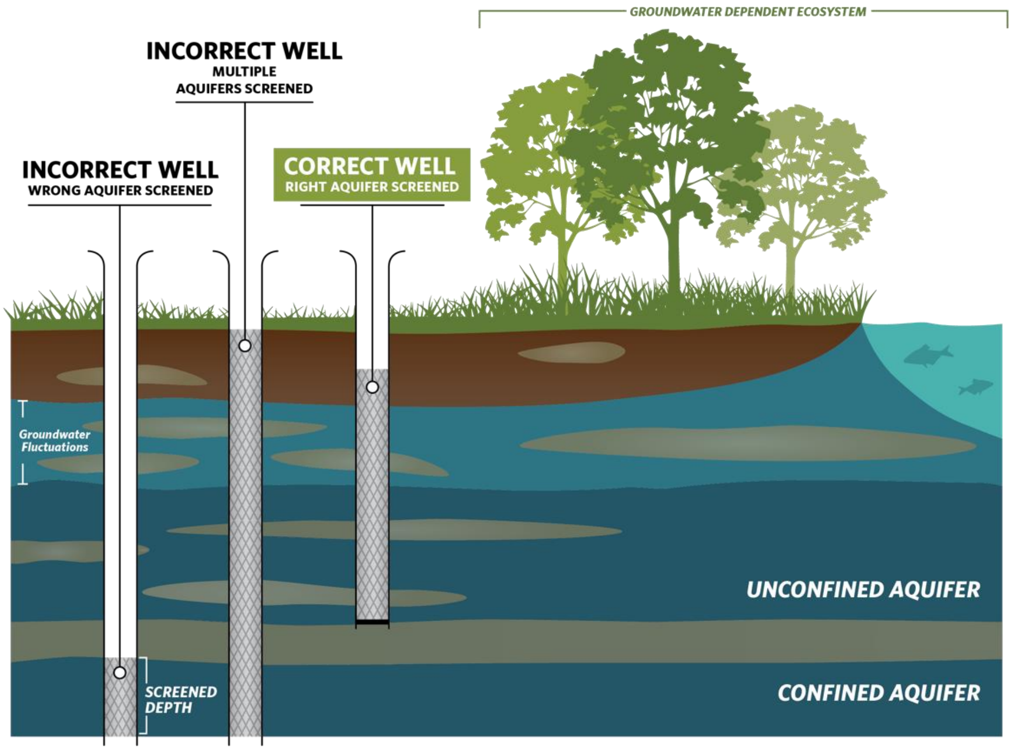

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

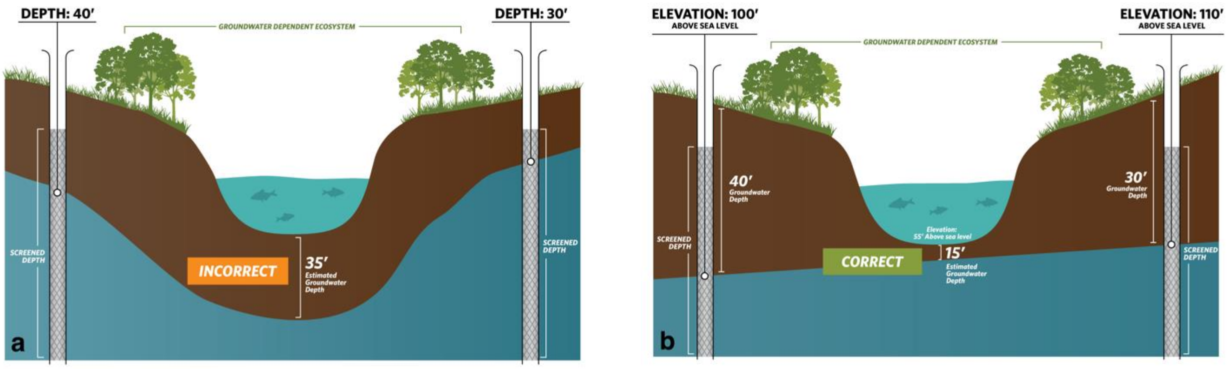

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

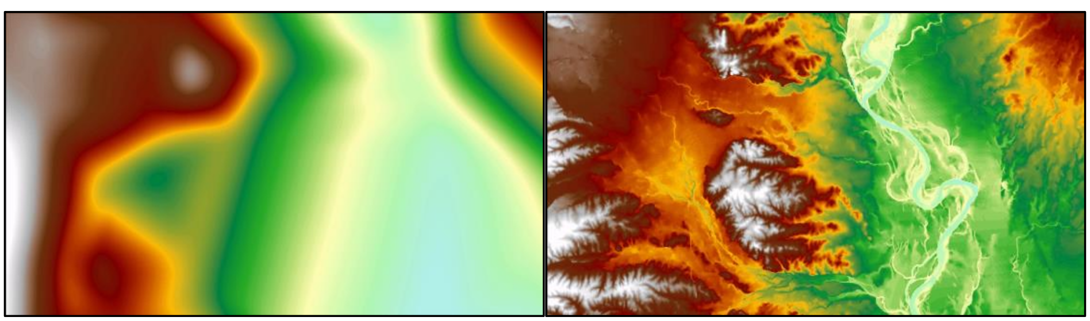

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[16] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

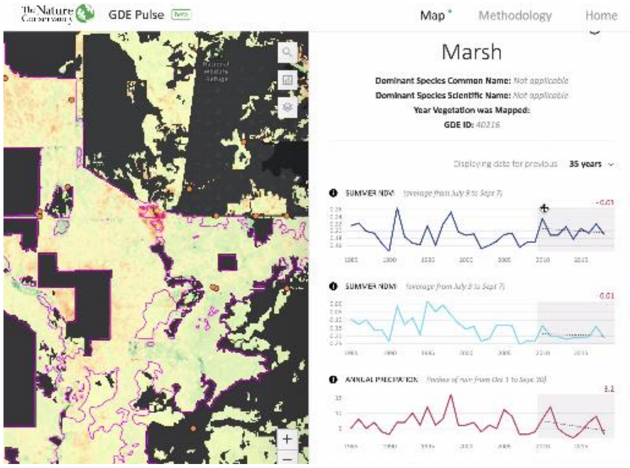
The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Attachment E

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

CALIFORNIA WATER | **GROUNDWATER**

June 3, 2020

California Department of Water Resources
Sustainable Groundwater Management Office

Submitted online via: https://sgma.water.ca.gov/portal/gsp/all

Re: Greater Kaweah Groundwater Sustainability Plan (GSP), Kaweah Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Greater Kaweah Groundwater Sustainability Agency's (GSA's) Greater Kaweah Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were unreasonable (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address gaps within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of potential ISW.

<u>Our Key Considerations</u>

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as only 1 out of 38 of our comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

<u>TNC recommendation</u>: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were not consistently or adequately analyzed in the GSP. The GSP provides a narrative description of surface water reaches in the Kaweah subbasin, but does not attempt to specify interconnected reaches or estimate the quantity and timing of streamflow depletions. Therefore, potential ISWs may not be managed in the GSP.

Map and Assessment of potential ISWs:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy's assessment has found that within the Greater Kaweah GSP, 0.7 river miles are likely to be gaining, 14.9 are likely to be losing, and the rest are uncertain or likely disconnected (based on streams with available groundwater depth data). Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on surface water-groundwater interconnectivity and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 2,784 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not adequately identify, map and consider GDEs. We believe that this does not meet plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on groundwater levels that were greater than 50 feet at a single point in time. While we appreciate the use of a more conservative groundwater depth threshold, this is a technically problematic approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unidentified and unprotected in the GSP.

TNC recommendation: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in Attachment D on best practices for utilizing the NC dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We would like to commend the GSP for including the groundwater demands of phreatophytes in the historical, current and projected water budgets. As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget. Please clarify if other categories of native vegetation and managed wetlands were included in the water budget, and include them if omitted.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid

[1] *Available at:* *https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf*

adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Potential GDEs are located in areas of the subbasin where no shallow groundwater monitoring currently exists or is proposed, leaving data gaps unfilled. Potential ISWs have been dismissed in the GSP, without proposed recommendations to improve ISW identification, mapping, and estimates of depletions. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

Attachment B

TNC Evaluation of the
Greater Kaweah Groundwater Sustainability Plan

A complete draft of the Greater Kaweah Groundwater Sustainability Plan (GSP) was provided for public review on September 16, 2019; TNC submitted comments on the Draft GSP on December 13, 2019. Public draft GSP comments and responses, provided as Attachment E of the GSP, were reviewed and are referred to below. The GSP comments and responses are also provided in Attachment F of this letter. We reviewed the responses to comments and the text of the Final GSP (dated January 22, 2020) to determine if changes were made to the Final GSP that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, and states whether or not they were addressed in the Final GSP *[as green text within brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

- *[Our comment was partially addressed. Section 1.4.1.10 was added with some background on the environmental groups that were consulted. The entities consulted were Tulare Basin Wildlife Partners and Sequoia Riverlands Trust. It is noted in Section 1.4.1.10 (p. 1-27) that "GKGSA has not identified environmental users of groundwater within the region."]* [Section 1.4.2 Beneficial Uses and Users (p. 1-20 to 1-23)]
    - Surface water users and the following groups were listed as Beneficial Users: "Environmental and ecosystem interests in GKGSA include the Tulare Basin Wildlife Partners and Sequoia Riverlands Trust" (p. 1-23). **Please identify whether or not the following beneficial uses and users of groundwater in the GSA are present: Protected Lands, including preserves, refuges, conservation areas, recreational areas; and other protected lands; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
    - The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the GSA should be specified. **To identify environmental users, please refer to the following:**
        - Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/
        - The list of freshwater species located in the Kaweah Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.
        - CDFW's California Natural Diversity Database (CNDDB) - https://www.wildlife.ca.gov/Data/CNDDB
        - USFWS's IPAC report for the GKGSA - https://ecos.fws.gov/ipac/

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8)

- [Section 1.3.6 Land Use Elements (p. 1-11 to 1-14)]
    - *[No GSP text changes were made in response to our comment.]* This section should include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**
    - *[No GSP text changes were made in response to our comment.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the GSA and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the GSA and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**
    - *[No GSP text changes were made in response to our comment.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the GSA. **Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**
- *[No GSP text changes were made in response to our comment.]* [Appendix 2A Section 2.3.1 Existing Groundwater Level Monitoring (p. 37-38)] The monitoring programs are described, but there is no mention of how GDEs are monitored and protected. **Please describe how existing groundwater monitoring programs are protective of GDEs, or propose additional monitoring that specifically targets GDEs.**
- *[No GSP text changes were made in response to our comment.]* [Appendix 2A Section 2.3.4 Existing Stream Flow Monitoring (p. 50)] This section describes the programs of USACOE, Kaweah and St. Johns Rivers Association (KSJRA) and the ditch companies. Surface water sources are listed along with the group monitoring them. Small surface streams which pass through TID's service area are noted as used, but the names are not listed. There is no mention of ISWs or GDEs and how they are monitored. **Please explain how existing stream flow monitoring is protective of ISWs and GDEs.**
- [Section 1.3.7.7 Well Construction Policies (p. 1-16)]
    - *[No GSP text changes were made in response to our comment.]* The GSP states (p. 1-16): "Tulare and Kings Counties have each adopted an ordinance for the construction of wells, based on California Well Standards as presented in DWR Bulletins 74-81 and 74-90." **Please include a discussion of how future well permitting will be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**

---

[2] The Critical Species LookBook is available at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

- *[No GSP text changes were made in response to our comment.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). **Compliance of well permitting programs with this requirement should be stated in the GSP.**

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Appendix 2A Section 2.2.4 Bottom of the Subbasin (p. 22)] The base of the Subbasin corresponds with the base of freshwater. "This is generally defined as the elevation below which total dissolved solids are greater than 2,000 milligrams per liter (mg/l) (Bertoldi et al, 1991)" (p. 22 of Appendix 2A). As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.
- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Appendix 2A Section 2.2.1.3 Kaweah Subbasin Geology (p. 17-21)] Basin-wide cross sections provided in Figures 4 through 13 are regional, and do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. **Please consider including an example near-surface cross section that depicts the conceptual understanding of shallow groundwater and stream interactions at different locations, including the Upper Aquifer, as well as any potential GDEs**.

Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Appendix 2A Section 2.9 Interconnected Surface Water (p. 145)] The discussion of interconnected surface waters should first be introduced in Appendix 2A Section 2.4 (Groundwater Elevation and Flow Conditions §354.16), since the identification of interconnected surface water systems is a required element of Current and Historical Groundwater Conditions (23 CCR §354.16). In Appendix 2A Section 2.4 (Groundwater Elevation and Flow Conditions §354.16), please expand this discussion, in particular:
    - The regulations [23 CCR §351(o)] define interconnected surface waters (ISW) as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is

not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. **Please identify interconnected surface waters in the GSA by relying on groundwater elevation and stream gauge data, specifying any data gaps that exist so that they can be resolved in the monitoring network.**

- ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface Digital Elevation Model that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. ISWs can be either gaining or losing. The defining feature of disconnected surface waters is that groundwater is consistently below surface water features such that an unsaturated zone always separates surface water from groundwater, not whether the reach is gaining or losing. **To improve ISW mapping, please reconcile data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features in the Monitoring Network section of the GSP.**

Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Appendix 2A Section 2.2.7.3 Delineation of recharge areas, potential recharge areas, and discharge areas, including springs, seeps, and wetlands (p. 33)], and [Appendix 2A Section 2.10 Groundwater Dependent Ecosystems (p. 146)] Both of the above referenced sections refer to or include discussion of the identification of groundwater dependent ecosystems (GDEs). **Please consolidate and expand these sections of the document in GSP Appendix 2A Section 2.4 (Groundwater Elevation and Flow Conditions §354.16), since the identification of groundwater dependent ecosystems (GDEs) is a required element of Current and Historical Groundwater Conditions (23 CCR §354.16)**. This is a more appropriate place for the identification of GDEs, since groundwater conditions (e.g., depth to groundwater, interconnected surface water maps, groundwater quality) are necessary local information and data from the GSP in assessing whether polygons in the NC dataset are connected to groundwater in a principal aquifer. For detailed guidance on how to address GDEs, please see our publication, *GDEs under SGMA: Guidance for Preparing GSPs*[3]. In particular, note the following:
  - *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* **Please provide a comprehensive discussion and figure(s) for the identification of GDEs**. Figure 19 of Appendix 2A is titled "Potential Groundwater Dependent Ecosystems", however the figure does not actually present this. The NC

[3]GDEs under SGMA: Guidance for Preparing GSPs is available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

dataset is a starting point for GSAs to identify GDEs in their area. The NC dataset comprises 3,488 acres of potential GDEs for the entire Kaweah Subbasin, representing a significant amount of GDEs to be considered. **Please map the original NC dataset on Figure 19 or another figure, and document which polygons were added (and what local sources were used to identify them), removed (and the removal reason), and kept (from the original NC dataset)**. The Subbasin's GDE shapefile, which is submitted via the SGMA Portal, should also include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were added or removed).

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* **Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network**. Specifically, please note:
  - *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* **Please provide depth to groundwater contour maps. See Attachment D for best practices for completing this step. Specifically, ensure that the first step is contouring groundwater elevations, and the subtracting this layer from land surface elevations from a Digital Elevation Model (DEM) to estimate depth to groundwater contours across the landscape**. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make.
  - *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* Figure 19 presents areas marked as 'Spring 2015 Groundwater Surface within 50 feet of Ground Surface'. Spring 2015 is after the SGMA benchmark date of January 1, 2015. **Please rely on groundwater condition data prior to the SGMA benchmark date**.
  - *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* It is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2015) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. **We highly recommend using depth to groundwater data from multiple seasons and**

water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer**. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network.**

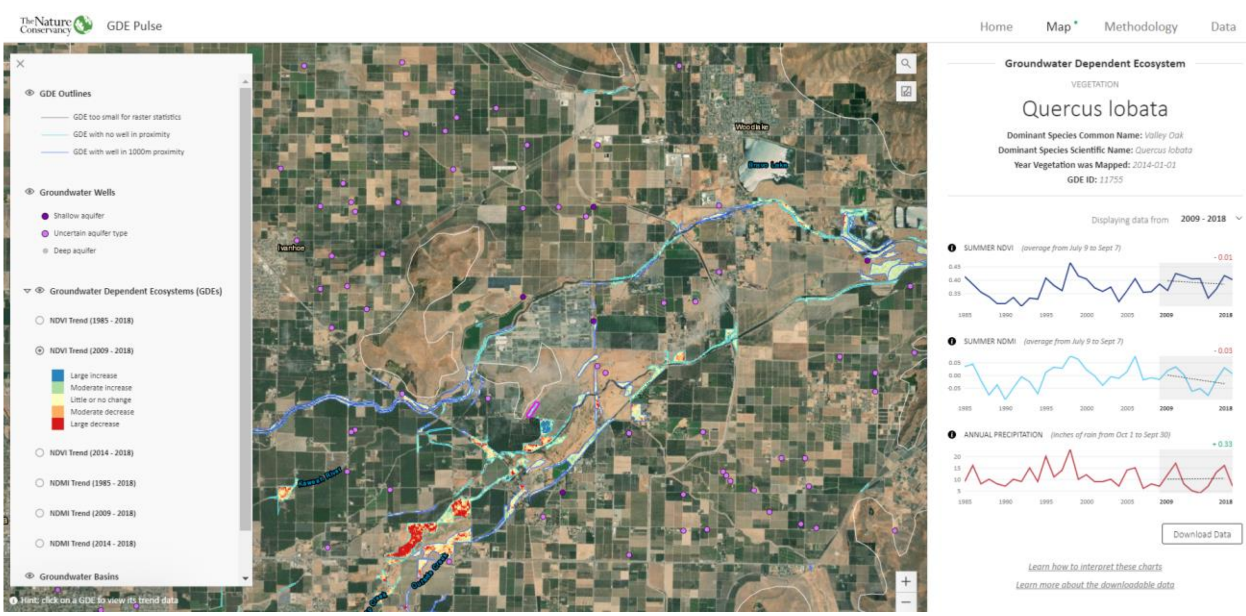
- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* **Please specify which data were used to determine the elevation of the stream or river bottom and the Valley Oak root zone in the GSA**. Page 5-18 states "The water table lies some 60 to 150 feet below the invert of all three of these channel reaches, which is generally 40 to 130 feet below the root zone of the Valley Oak", however no information is provided on the data used to determine the elevation of the stream or river bottom and these calculations. These depths suggest a root zone of approximately 20 feet, but this is not stated explicitly. Data cited in Lewis and Burgy (1964)[4] indicate root zones deeper than 70 feet for this species in a fractured rock aquifer. Rooting depths for the Valley Oak in this region have not been reported and thus are a data gap. Furthermore, care must be taken when considering rooting depths of vegetation. Rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant. Maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not prefer to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths. In addition, while it is likely to be true that shallow water availability is necessary to support the recruitment of saplings, hydraulic lift of groundwater to shallow depths has been observed in Quercus spp.
- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* Page 33 of Appendix 2A states "The locations of these potential GDEs and hydrographs for the Subbasin indicate that the vegetation of these areas are dependent [on] surface water flows, rather than shallow groundwater." We disagree with this statement dismissing all potential GDEs from further consideration. There are 3,488 acres of potential GDEs within the Kaweah Subbasin as per the NC dataset, and the location is, as to be expected, at the interconnection between groundwater and surface water. Adverse impacts can occur to GDEs due to pumping that further separates groundwater from surface

[4] Lewis, D.C. and Burgy, R.H., 1964. The relationship between oak tree roots and groundwater in fractured rock as determined by tritium tracing. Journal of Geophysical Research, 69(12), pp. 2579-2588.

water. **Please provide the rationale for this statement, including the discussion of the type of river reach (i.e., gaining or losing)**. Riparian vegetation may still be accessing groundwater, and hence be identified as a GDE. We highly recommend that depth to groundwater levels under the NC polygons be used as the evaluation criteria, since access to groundwater could be occurring in/near losing reaches. **Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. Specifically, it is highly advised that fluctuations in the groundwater regime be characterized in space and time to understand the seasonal and interannual groundwater variability in GDEs.**

<u>Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)</u>

- [Appendix 2A Section 2.10 Groundwater Dependent Ecosystems (p. 146)]
    - *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* **Once potential GDEs are identified, please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present**. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the Greater Kaweah GSA:



- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* **Once potential GDEs are identified, provide an inventory of the vegetation types or habitat types and rank the vegetation species as having a high, moderate or low value. Please identify whether any endangered or threatened freshwater species of animals and plants or areas with critical habitat were found in any of the GDEs**. The list of freshwater species located in the Kaweah Subbasin can be found in Attachment C of this letter.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

- *[Our comment was addressed. Phreatophyte extraction is defined in the final GSP. This element was added to the water budget, and it is noted that this is a minor component of the water budget. This is presented in Table 30 (p. 102) of Appendix 2A.]* Please clarify what the term "phreatophyte extraction' means. The text states 'Phreatophyte extraction consists of removing vegetation in riparian areas to prevent consumptive water use." If phreatophytes were indeed removed from within the Subbasin, please provide further details. If phreatophyte extraction refers to the uptake of groundwater by phreatophytes, then correct this text. It should be clearly stated if the phreatophytes referred to are potential GDE vegetation.
- *[No GSP text changes were made in response to our comment.]* **Please clarify what assumptions and data were used to calculate the outflow term from groundwater by phreatophytes.**

<u>Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)</u>

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 3.3 Sustainability Goal (p. 3-2)] "The broadly stated sustainability goal for the Kaweah Subbasin as agreed to by the three GSAs therein is, for each GSA to manage groundwater resources to preserve the quality of life through maintaining the viability of existing enterprises of the region, both agricultural and urban." There is no mention of protection of environmental users including ISWs or GDEs. **Please rephrase the Sustainability Goal to specifically call out all beneficial uses and users of groundwater including environmental users, state how the sustainability of environmental uses will be protected, and expand the goal to include protection of GDEs, ISWs, and critical habitats.**

<u>Checklist Item 26 – Measurable Objectives (23 CCR §354.30)</u>

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 5.2 General Approach (p. 5-1)] Refer to Comments on Checklist Items 8-10 above on the existence of ISWs in the GSA. The GSP seeks to establish non-applicability of the ISW SMC (Table 5-1) and thus the GSP fails to establish Sustainable Management Criteria for this sustainability indicator. However, the existence of potential riparian

GDEs along the streams in the Subbasin has been identified in Appendix 2A, and their connection to groundwater is assumed. Their occurrence in the riparian zone means that these GDEs should be considered a beneficial user of groundwater that could be affected by chronic groundwater level decline as discussed above, as well as beneficial users of surface water that could be depleted by groundwater extraction. **Please include a discussion of Sustainable Management Criteria for ISWs, including Measurable Objectives, in the GSP. A more robust discussion of the known facts regarding these surface-groundwater interactions in the riparian zone should be provided. Please cite data gaps regarding ISWs and make plans to reconcile them in the Monitoring Section of the GSP.**

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 5.3.2 Measurable Objectives for Groundwater Levels (p. 5-10 to 5-11)] The measurable objective was set equal to the water level at 2030 using the 2006-2016 water level trend for each of the wells selected as representative monitoring sites. The specific measurable objectives for all of the selected wells are listed in Table 5-3 (p. 5-6). **Please explain how the Measurable Objectives will help achieve the Sustainability Goal as it pertains to the environment. After GDEs and ISWs are identified, please discuss if any impacts to GDEs or ISWs are expected. Data gaps should be noted and addressed in the Monitoring section.**

<u>Checklist Items 27 to 29 – Minimum Thresholds (23 CCR §354.28)</u>

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 5.2 General Approach (p. 5-1)] **Following the discussion presented above for Checklist Item 26 (Measurable Objectives), please include a discussion of Sustainable Management Criteria for ISWs, including Minimum Thresholds, in the GSP. Please cite data gaps regarding ISWs and make plans to reconcile them in the Monitoring Section of the GSP.**
- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 5.3.1 Minimum Threshold for Groundwater Levels (p. 5-2 to 5-10)] The trend of the 2006-2016 water levels over time was used to set the Minimum Threshold at 2040 for each of the wells, used as representative monitoring sites, in each of eight hydrogeologic zones within the Subbasin (shown on Figure 5.1, p. A5-1). The Minimum Thresholds and other Sustainable Management Criteria for each well are listed in Table 5-3 (p. 5-6). **Please explain how the Minimum Thresholds will help achieve the Sustainability Goal as it pertains to the environment. After GDEs and ISWs are identified, please discuss if any impacts to GDEs or ISWs are expected. Data gaps should be noted and addressed in the Monitoring section.**

<u>Checklist Items 30 to 46 – Undesirable Results (23 CCR §354.26)</u>

- [Section 3.4 Groundwater Levels Undesirable Results (p. 3-4)] After the identification and evaluation of potential GDEs is completed, this section should discuss impacts to those GDEs. Specifically,
    - *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* For chronic lowering of water level, the GSP Committee considered that one-third of the representative monitoring sites (wells) exceeding minimum thresholds for water levels would constitute an undesirable result. There appears to be no additional guidance to protect potential GDEs or ISWs. Damage to GDEs can occur within a relatively short period of time and can be irreversible, leading to the permanent loss of a protected resource. A fractional violation trigger is therefore inadequate to assure that the environmental users are protected. **Please elaborate on how the exceedance criteria would be applied in a way that is protective of significant and unreasonable harm to GDEs. Consider the use of separate management areas for the GDE Units, so that Sustainable Management Criteria protective of GDEs can be established for the GDE Units.** A procedure could be included for violation of Minimum Thresholds that includes early identification of potential GDE impacts and appropriate response actions. This could be accomplished efficiently and cost-effectively using remote sensing tools, such as GDE Pulse.
    - *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* **Please provide more specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs.** The definition of 'significant and unreasonable' is a qualitative statement that is used to describe when undesirable results would occur in the GSA, such that a minimum threshold can be quantified. Potential effects on all beneficial users of groundwater in the GSA need to be taken into consideration. According to the California Constitution Article X, §2, water resources in California must be "put to beneficial use to the fullest extent of which they are capable". **Please identify appropriate biological indicators that can be used to monitor potential impacts to environmental beneficial users due to groundwater conditions. Refer to Appendix E of this letter for an overview of GDE Pulse.**
    - *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* The GSP states (p. 3-5): "The potential effects of lowered groundwater levels, when approaching or exceeding minimum thresholds and thus becoming an Undesirable result, are reduced irrigation water supplies for agriculture and for municipal systems through loss of well capacity, loss or degradation of water supplies for smaller community water systems and domestic wells due to well failures, increased energy consumption due to lowered water levels, and the adverse economic consequences of the aforementioned effects such as increased energy usage to extract groundwater from deeper levels." The impacts of lowered groundwater levels on environmental users are not discussed. **Please add**

adverse impacts to environmental users of groundwater to the list of Undesirable Results as presented in this paragraph.

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 3.8 Interconnected Surface Waters Undesirable Results (p. 3-10)] The GSP states (p. 3-10): "No interconnected surface waters have been identified in any Kaweah Subbasin GSAs as described more thoroughly in the basin setting. Thus, criteria were not established." **Once ISWs are analyzed per our comments on Checklist Items 8-10 above, please revise this section, noting any data gaps to be filled.**

<u>Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)</u>

- *[This comment was partially addressed. The need for additional monitoring is noted in Section 4.10.1.1 and 4.10.1.4, but no specific locations or depths are indicated in the Final GSP. These activities are noted to be addressed in future work.]* [Section 4.4 Groundwater Level Monitoring Network (p. 4-9 to 4-14)] Appendix 2A (p. 146) states: "As presented on Figure 19, areas where groundwater is within 50 feet of the ground surface are located along the Kaweah River (Greater Kaweah GSA) and in two areas within the East Kaweah GSA. Notably, these represent areas where groundwater elevations as of the Spring of 2015 has risen to within 50 feet of the ground surface. The indicated areas are preliminary and subject to review of the local GSAs, who know better which areas can be considered Potential GDEs. This can be addressed as part of a further study." However, the monitoring proposed in Chapter 4 does not address this acknowledged data gap. The representative groundwater level monitoring sites shown on Figure 4-3 do not provide adequate coverage of the areas of potential GDEs. **Please address the noted data gap by describing any additional monitoring of locations where potential GDEs occur.**
- *[This comment was partially addressed. The need for additional monitoring is noted in Section 4.10.1.1 and 4.10.1.4, but no specific locations or depths are indicated in the Final GSP. These activities are noted to be addressed in future work.]* [Section 4.8 Depletions of Interconnected Surface Water Monitoring Network (p. 4-17 to 4-18)] Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *<u>and related surface conditions</u>* (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of complex factors, and this relationship is not characterized or discussed. The GSP states (p. 4-18): "As stated previously, current data show that interconnected surface waters are not present in the Kaweah Subbasin due to groundwater levels already being so low. However, to confirm that conditions are not significantly changing in areas with potential GDEs and a depth to groundwater less than 50 ft, groundwater level monitoring shall be implemented along the Kaweah and St. Johns Rivers in the forebay area of the upper reaches." Furthermore, the GSP states (p. 4-21 and 4-22 under Data Gaps): "As part of addressing the data gap of spatial distribution for

SGMA-compliant groundwater level monitoring, the GKGSA and other GSAs of the Kaweah Subbasin will coordinate for the installation of SGMA-compliant groundwater level monitoring to validate existing data and confirm whether or not Interconnected Surface Waters are present in the Kaweah Subbasin in proximity to the Kaweah and St. Johns Rivers."   As noted above, data gaps have also been noted regarding the existence of GDEs. In addition to the need for additional shallow monitoring wells in the upper aquifer to map GDEs, **there is also a need to enhancing monitoring of stream flow and vertical groundwater gradients by installing more stream gauges and clustered/nested wells near streams, rivers or wetlands.** Ideally, co-locating stream gauges with wells that can monitor groundwater levels in both the upper and lower aquifers would enhance understanding about where ISWs exist in the GSA and whether pumping is causing depletions of surface water or impacts on beneficial users of surface water and groundwater. **Please provide sufficient detail for the investigation and monitoring program including stream gauges, screened intervals and frequency of monitoring, in order to describe monitoring of both the extent of ISWs and the quantity of surface water depletions from ISWs.**

- *[No GSP text changes were made in response to our comment.]* [Section 8.1 Annual Reporting Summary to DWR (p. 8-1 to 8-3)] The GSP states (p. 8-3): "Groundwater contour maps submitted during the first five years may reflect a composite of the principal aquifers within the subbasin due to data gaps as discussed in the Basin Setting Report (Appendix 2A) of this Plan. As additional dedicated monitoring wells are installed, and as more knowledge is gained regarding subbasin hydrogeology, groundwater conditions within each separate aquifer will be better understood." **Please discuss the importance of a groundwater elevation map prepared for the Upper Aquifer above the Corcoran Clay**, as that is the only way to determine the appropriate depth relationships between surface water and groundwater which are needed to designate a GDE. Mixing shallow and deep wells, particularly when confined conditions may be present, can be misleading.

<u>Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)</u>

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 7 Projects, Management Actions, and Adaptive Management (p. 7-1)] The GKGSA includes GDEs and ISWs (see our comments under Checklist Items 8-10 and 16-20 above) that are beneficial environmental uses and users of groundwater and may include potentially sensitive resources and protected lands. Environmental beneficial users and uses should be considered in establishing project priorities. In addition, consistent with existing grant and funding guidelines for SGMA-related work, consideration should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**
- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 7.2 Projects (p. 7-

1)] This section identifies recharge projects; however, the descriptions of Measurable Objectives for these projects typically identifies benefits to water level, groundwater storage, and degraded water quality but not to interconnected surface waters. In some cases, the water source and the funding have not been identified, increasing the uncertainty of the project being implemented. Because maintenance or recovery of groundwater levels or construction of recharge facilities may have potential environmental benefits, it would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.

  - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
  - If ISWs will not be adequately protected by those listed, **please include and describe additional projects and management actions targeted for protecting ISWs.**
  - Recharge basins, reservoirs and facilities for managed stormwater recharge projects can be designed as multi-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such multiple-benefit projects and facilities have been incorporated into local Habitat Conservation Plans (HCPs) and Natural Community Conservation Plans (NCCPs), more fully recognizing the value of the habitat that they provide and the species they support. **For projects that construct recharge basins, please consider identifying if there is habitat value incorporated into the design and how the recharge basins could be managed to benefit environmental users**. Grant and funding priorities for SGMA-related work may be given to multi-benefit projects that can address water quantity as well as provide environmental benefits. **Therefore, please include environmental benefits and multiple benefits as criteria for assessing project priorities.**
  - For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

- *[No GSP text changes were made in response to our comment. It is noted in Attachment E that this will be addressed in future work.]* [Section 7.3 Management Actions (p. 7-52)] The GKGSA has listed possible management actions in Section 7.3 of the GSP. These actions include communication and engagement. **Please consider adding Management Actions which include education and outreach for protection of GDEs and ISWs as well as specific management of these ecosystems and the species they provide for.**

Attachment C

Freshwater Species Located in the Kaweah Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Kaweah Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[5]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[6] as well as on The Nature Conservancy's science website[7].

Scientific Name	Common Name	Legally Protected Species		
		Federal	State	Other
Birds				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	Bird of Conservation Concern	Special Concern	BSSC - First priority
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anas strepera	Gadwall			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron			
Aythya affinis	Lesser Scaup			
Aythya americana	Redhead		Special Concern	BSSC - Third priority
Aythya collaris	Ring-necked Duck			
Aythya marila	Greater Scaup

Aythya valisineria	Canvasback		Special	
Botaurus lentiginosus	American Bittern			
Bucephala albeola	Bufflehead			
Bucephala clangula	Common Goldeneye			
Butorides virescens	Green Heron			
Calidris alpina	Dunlin			
Calidris mauri	Western Sandpiper			
Calidris minutilla	Least Sandpiper			
Chen caerulescens	Snow Goose			
Chen rossii	Ross's Goose			
Chlidonias niger	Black Tern		Special Concern	BSSC - Second priority
Chroicocephalus philadelphia	Bonaparte's Gull			
Cistothorus palustris palustris	Marsh Wren			
Cygnus columbianus	Tundra Swan			
Cypseloides niger	Black Swift	Bird of Conservation Concern	Special Concern	BSSC - Third priority
Egretta thula	Snowy Egret			
Empidonax traillii	Willow Flycatcher	Bird of Conservation Concern	Endangered	
Fulica americana	American Coot			
Gallinago delicata	Wilson's Snipe			
Grus canadensis	Sandhill Crane			
Haliaeetus leucocephalus	Bald Eagle	Bird of Conservation Concern	Endangered	
Himantopus mexicanus	Black-necked Stilt			
Icteria virens	Yellow-breasted Chat		Special Concern	BSSC - Third priority
Ixobrychus exilis hesperis	Western Least Bittern		Special Concern	BSSC - Second priority
Limnodromus scolopaceus	Long-billed Dowitcher			
Lophodytes cucullatus	Hooded Merganser			
Megaceryle alcyon	Belted Kingfisher			
Mergus merganser	Common Merganser			
Mergus serrator	Red-breasted Merganser			
Numenius americanus	Long-billed Curlew			
Numenius phaeopus	Whimbrel			
Nycticorax nycticorax	Black-crowned Night-Heron			
Oxyura jamaicensis	Ruddy Duck			

Pelecanus erythrorhynchos	American White Pelican		Special Concern	BSSC - First priority
Phalacrocorax auritus	Double-crested Cormorant			
Phalaropus tricolor	Wilson's Phalarope			
Plegadis chihi	White-faced Ibis		Watch list	
Pluvialis squatarola	Black-bellied Plover			
Podiceps nigricollis	Eared Grebe			
Podilymbus podiceps	Pied-billed Grebe			
Porzana carolina	Sora			
Rallus limicola	Virginia Rail			
Recurvirostra americana	American Avocet			
Riparia riparia	Bank Swallow		Threatened	
Setophaga petechia	Yellow Warbler			BSSC - Second priority
Tachycineta bicolor	Tree Swallow			
Tringa melanoleuca	Greater Yellowlegs			
Tringa semipalmata	Willet			
Tringa solitaria	Solitary Sandpiper			
Xanthocephalus xanthocephalus	Yellow-headed Blackbird		Special Concern	BSSC - Third priority
		Crustaceans		
Branchinecta lynchi	Vernal Pool Fairy Shrimp	Threatened	Special	IUCN - Vulnerable
Lepidurus packardi	Vernal Pool Tadpole Shrimp	Endangered	Special	IUCN - Endangered
		Fishes		
Catostomus occidentalis occidentalis	Sacramento sucker			Least Concern - Moyle 2013
Cottus gulosus	Riffle sculpin		Special	Near-Threatened - Moyle 2013
Lampetra hubbsi	Kern brook lamprey		Special Concern	Vulnerable - Moyle 2013
Lavinia exilicauda exilicauda	Sacramento hitch		Special	Near-Threatened - Moyle 2013
Lavinia symmetricus symmetricus	Central California roach		Special Concern	Near-Threatened - Moyle 2013
Mylopharodon conocephalus	Hardhead		Special Concern	Near-Threatened - Moyle 2013
Oncorhynchus mykiss irideus	Coastal rainbow trout			Least Concern - Moyle 2013
Orthodon microlepidotus	Sacramento blackfish			Least Concern - Moyle 2013
Ptychocheilus grandis	Sacramento pikeminnow			Least Concern - Moyle 2013

Herps				
Actinemys marmorata marmorata	Western Pond Turtle		Special Concern	ARSSC
Ambystoma californiense californiense	California Tiger Salamander	Threatened	Threatened	ARSSC
Anaxyrus boreas boreas	Boreal Toad			
Rana boylii	Foothill Yellow-legged Frog	Under Review in the Candidate or Petition Process	Special Concern	ARSSC
Spea hammondii	Western Spadefoot	Under Review in the Candidate or Petition Process	Special Concern	ARSSC
Taricha torosa	Coast Range Newt		Special Concern	ARSSC
Thamnophis couchii	Sierra Gartersnake			
Thamnophis sirtalis sirtalis	Common Gartersnake			
Insects and Other Invertebrates				
Eulimnichus analis				Not on any status lists
Ischnura barberi	Desert Forktail			
Mammals				
Castor canadensis	American Beaver			Not on any status lists
Lontra canadensis canadensis	North American River Otter			Not on any status lists
Ondatra zibethicus	Common Muskrat			Not on any status lists
Mollusks				
Physella virgata	Protean Physa			CS
Plants				
Alnus rhombifolia	White Alder			
Ammannia coccinea	Scarlet Ammannia			
Anemopsis californica	Yerba Mansa			
Azolla filiculoides	NA			
Baccharis glutinosa	NA			Not on any status lists
Bidens laevis	Smooth Bur-marigold			
Carex densa	Dense Sedge			
Cephalanthus occidentalis	Common Buttonbush			
Cyperus acuminatus	Short-point Flatsedge			
Cyperus erythrorhizos	Red-root Flatsedge			
Downingia bella	Hoover's Downingia			

Echinodorus berteroi	Upright Burhead			
Eleocharis macrostachya	Creeping Spikerush			
Epilobium cleistogamum	Cleistogamous Spike-primrose			
Eryngium pinnatisectum	Tuolumne Coyote-thistle		Special	CRPR - 1B.2
Eryngium spinosepalum	Spiny Sepaled Coyote-thistle		Special	CRPR - 1B.2
Eryngium vaseyi vaseyi	Vasey's Coyote-thistle			Not on any status lists
Euthamia occidentalis	Western Fragrant Goldenrod			
Lasthenia ferrisiae	Ferris' Goldfields		Special	CRPR - 4.2
Lasthenia fremontii	Fremont's Goldfields			
Leersia oryzoides	Rice Cutgrass			
Lemna minor	Lesser Duckweed			
Ludwigia peploides peploides	NA			Not on any status lists
Marsilea vestita vestita	NA			Not on any status lists
Mimulus cardinalis	Scarlet Monkeyflower			
Mimulus guttatus	Common Large Monkeyflower			
Mimulus tricolor	Tricolor Monkeyflower			
Myosurus minimus	NA			
Myriophyllum hippuroides	Western Water-milfoil			
Orcuttia inaequalis	San Joaquin Valley Orcutt Grass	Threatened	Endangered	CRPR - 1B.1
Paspalum distichum	Joint Paspalum			
Phyla nodiflora	Common Frog-fruit			
Plagiobothrys acanthocarpus	Adobe Popcorn-flower			
Platanus racemosa	California Sycamore			
Puccinellia simplex	Little Alkali Grass			
Rumex occidentalis				Not on any status lists
Sagina saginoides	Arctic Pearlwort			
Salix exigua exigua	Narrowleaf Willow			
Salix gooddingii	Goodding's Willow			
Salix laevigata	Polished Willow			
Salix lasiolepis lasiolepis	Arroyo Willow			
Stachys albens	White-stem Hedge-nettle			
Typha domingensis	Southern Cattail			
Typha latifolia	Broadleaf Cattail

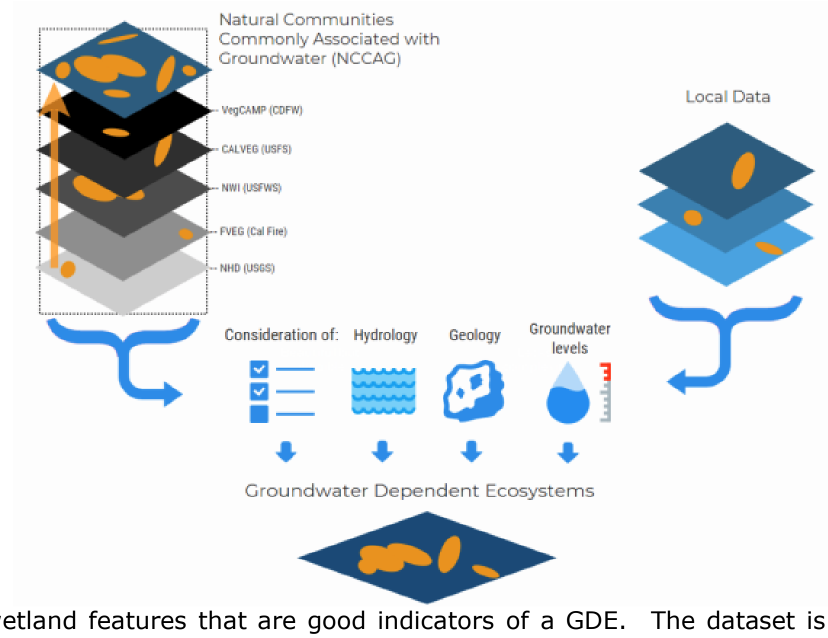
July 2019

IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[8] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[9]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48

---

[8] *NC Dataset Online Viewer:* *https://gis.water.ca.gov/app/NCDatasetViewer/*
[9] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[10]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[11] on the Groundwater Resource Hub[12], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

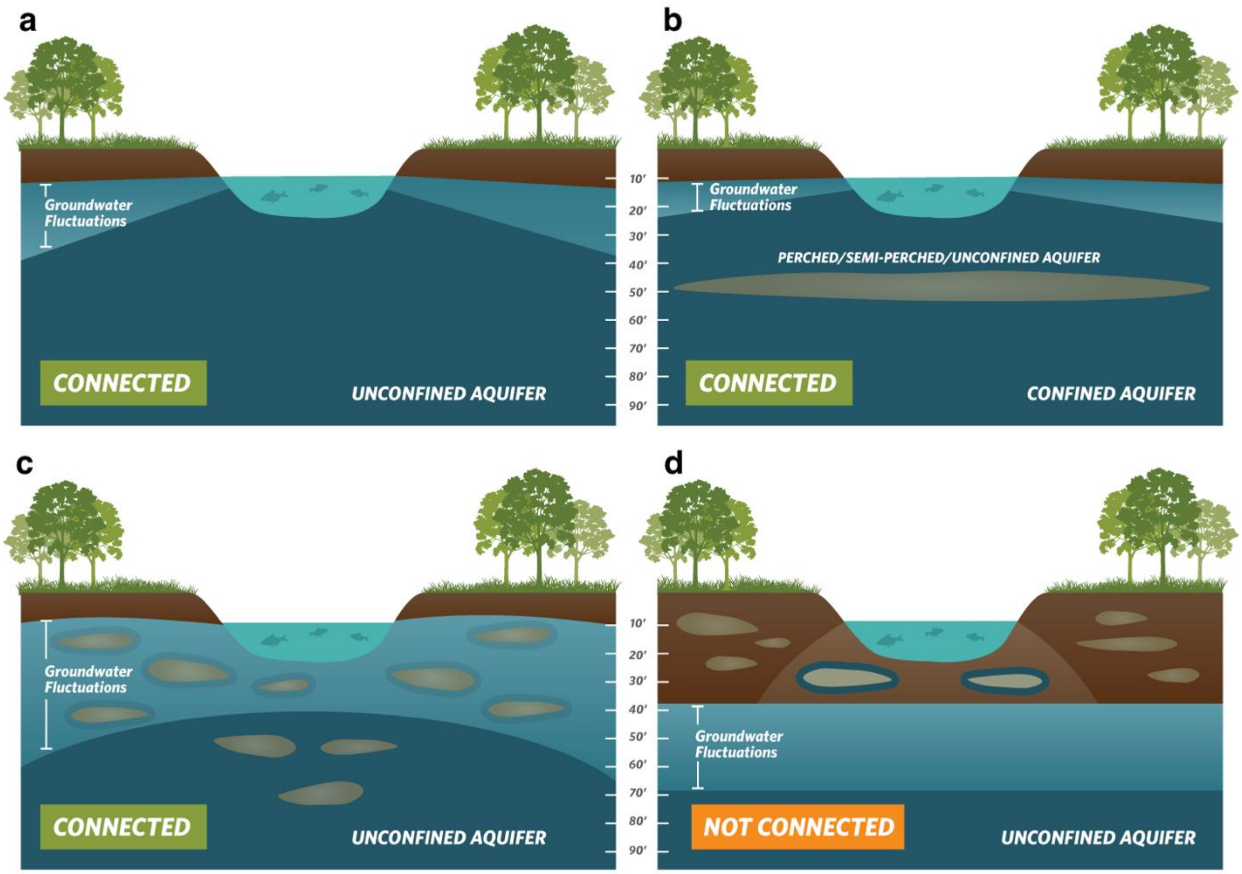

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[13] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[14] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[15] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[16]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

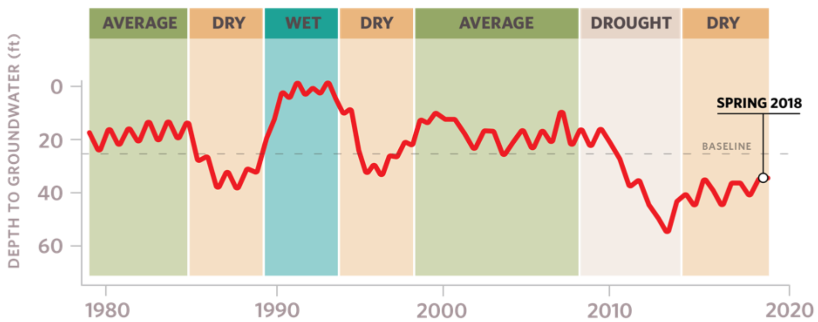

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[14] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[15] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[16] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[17], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

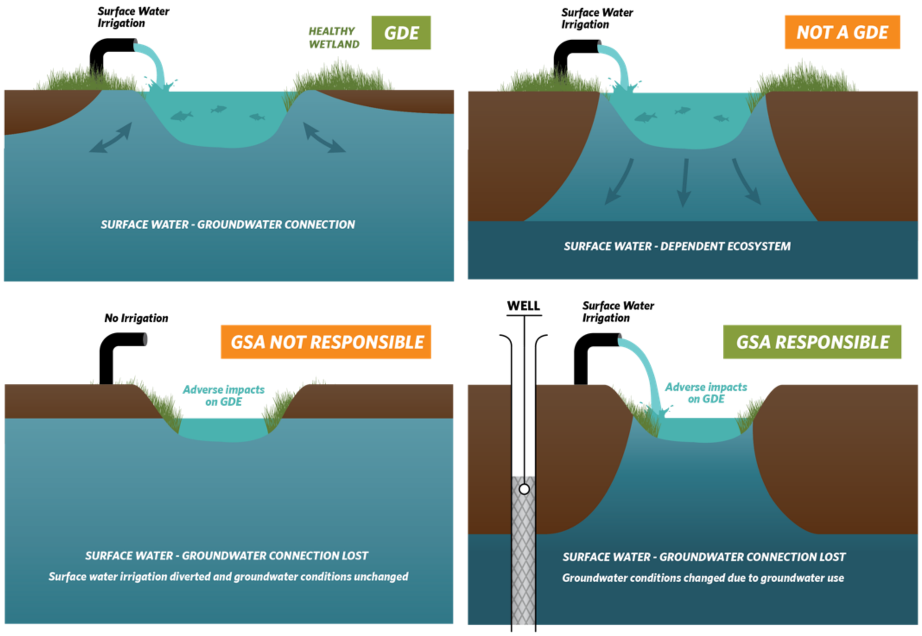

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[17] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

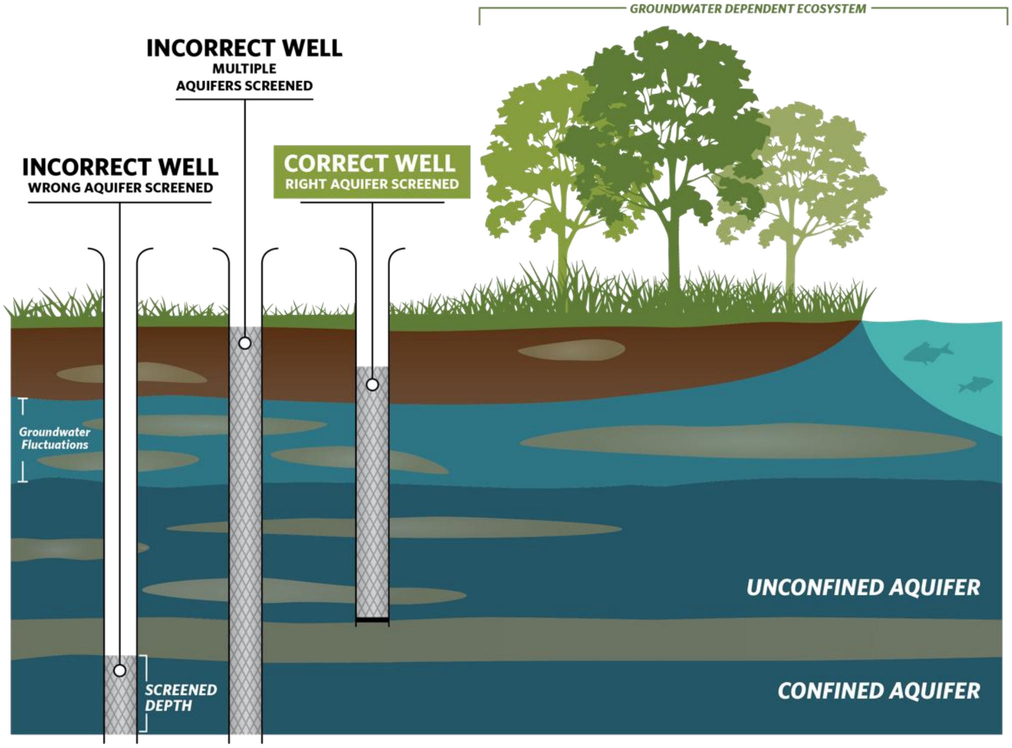

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[18] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

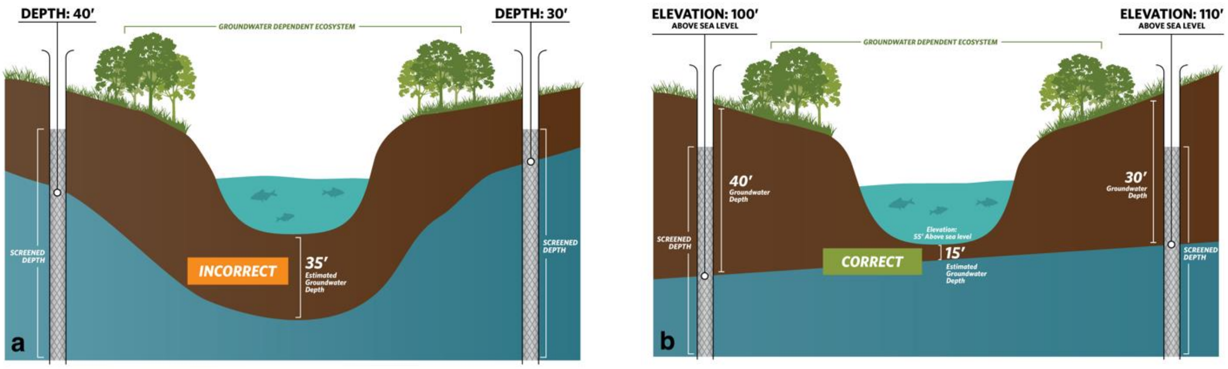

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

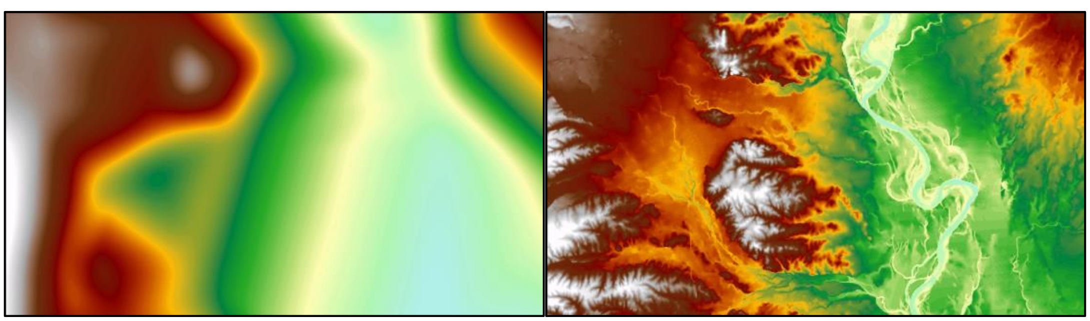

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

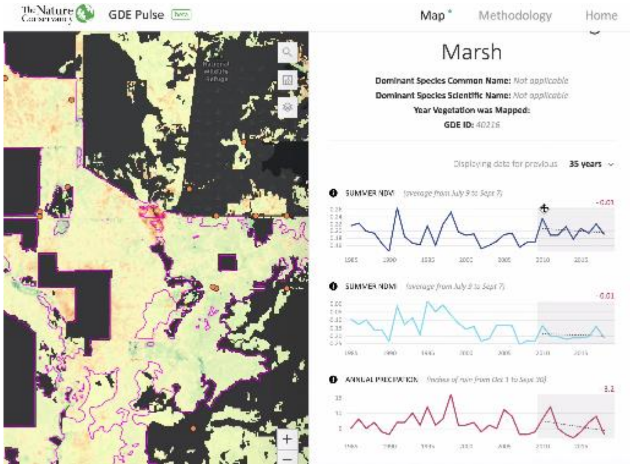
Protecting nature. Preserving life.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[19]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[20]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Attachment G

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2011-2018)

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[21]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[22]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[23] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Indian Wells Valley Groundwater Sustainability Plan (GSP), Indian Wells Valley Basin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Indian Wells Valley Groundwater Authority's Indian Wells Valley Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be incomplete in addressing environmental beneficial uses and users.

While the GSP addressed environmental beneficial users in some respects, our review finds that portions of the GSP should be remedied before being approved. Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some case, it may be difficult to address gaps within 180 days. In these cases, we strongly recommend that the Department set clear expectations that these be corrected in the 2025 plan update, and to the degree that gaps are due to lack of data, that these data gaps be addressed to inform the 2025 update.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP.

<u>Our Key Considerations</u>

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section.

We are disappointed to see the feedback that we provided on the draft GSP has been largely ignored in the final plan, as only 5 out of 40 comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

<u>TNC recommendation</u>: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were excluded based on the ephemeral nature of streams in the valley, yet there is very little description or analysis of the interaction between principal aquifers and surface expression of groundwater. Therefore, potential ISWs are not being managed in the GSP.

<u>TNC recommendation</u>: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on groundwater and surface water interconnectivity, and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 15,021 acres of potential GDEs occur in the GSA boundary. TNC developed the Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

[1] *Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf*

We were pleased to see that GDEs were identified and mapped and presented in the GSP by species type. Additionally, the GSP discusses additional data from the November 2018 field visit and the US Navy mapping of GDEs on NAWS China Lake. Despite these positive steps towards identification of GDEs, the GSP did not adequately consider GDEs as a beneficial user throughout the plan. We recommend that the GSP be revised to consider GDEs as a beneficial user, especially in determining undesirable results, minimum thresholds and measurable objectives.

Water Budget – We would like to commend the GSP for including the groundwater demands of native vegetation in the historical, current and projected water budgets.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

<u>TNC recommendation</u>: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs, including regional springs). In addition, the GSP should confirm that minimum thresholds for ISWs, including regional springs, avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Potential GDEs are located in areas of the basin where no shallow groundwater monitoring currently exists. While the GSP discusses this data gap, no specific plans for further monitoring are provided. Potential ISWs have also been excluded in the GSP, without proposed monitoring to confirm connectivity, advance mapping, and estimate depletions. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

<u>TNC recommendation</u>: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Attachment A

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

* In reference to DWR's GSP annotated outline guidance document, available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/GD_GSP_Outline_Final_2016-12-23.pdf

Attachment B

TNC Evaluation of the
Indian Wells Valley Groundwater Sustainability Plan

A complete draft of the Indian Wells Valley Groundwater Sustainability Plan (GSP), adopted in January 2020, was reviewed by TNC. Responses to comments are provided in Appendix 1-F of the Final GSP. The response to comments is also provided in Attachment F of this letter. We reviewed the responses to comments and the text of the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the Indian Wells Valley Groundwater Authority during the public comment period, and states whether or not they were addressed in the Final GSP *[as green text within brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

<u>Checklist Item 1 - Notice & Communication (23 CCR §354.10)</u>

[Section 1.3 Beneficial Uses and Users (p. 1-3 to 1-4)]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* We appreciate that the beneficial uses and users of groundwater stated in the GSP include "Environmental (including wildlife habitat and Groundwater Dependent Ecosystems)" (p. 1-4). Users of groundwater, including DACS, SDACs, economically distressed areas, businesses, large and small-scale agriculture, domestic users, federal, state and local agencies, tribal groups, non-profit organizations, community organizations, and environmental groups, were identified during the development of the GSP. The listing of over 150 stakeholders is included as Appendix 1-D, and the Communications & Engagement Plan is provided in Appendix 1-E. **Please identify whether or not the following beneficial uses and users of groundwater are present: Protected Lands, including refuges, conservation areas, and recreational areas; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* The types and locations of environmental uses, species and habitats supported, instream flow requirements, and other designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the Basin should be specified. **To identify environmental users, please refer to the following:**
    - The NC Dataset (https://gis.water.ca.gov/app/NCDatasetViewer/) which identifies potential presence of groundwater dependent ecosystems in this basin.

- The list of freshwater species located in the Indian Wells Valley Basin in Attachment C of this letter. Please take particular note of the species with protected status.
- CDFW's California Natural Diversity Database (CNDDB) - https://www.wildlife.ca.gov/Data/CNDDB
- USFWS's IPAC report for the Indian Wells Valley Area, if available - https://ecos.fws.gov/ipac/

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8)

[Section 2.5.2 Summary of General Plans and Other Land Use Plans (p. 2-15 to 2-24)]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* The Kern, Inyo and San Bernardino Counties General Plans were adopted prior to the development of the Indian Wells Valley Groundwater Authority. The provided summaries of the plans emphasize policies that relate to water supply and groundwater, but do not include discussion of goals and policies related to the protection and management of GDEs that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of aquatic habitats and other environmental users.**

[Section 2.6 Existing Water Resources Monitoring Programs (p. 2-25 to 2-27)]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* Locations of monitoring wells in the IWV Groundwater Basin are shown on Figure 2-13, but there is no listing of well attributes such as screened interval or well depth. **Please provide a table with well construction information for the wells currently monitored.**

[Section 2.7.7 Well Permitting and Procedures (p. 2-38 to 2-42]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* Well permitting is handled by Kern, Inyo, and San Bernardino counties, the three counties that encompass the basin. **Please include a discussion of how future well permitting will be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**
- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF vs. SWRCB and Siskiyou County, No. C083239). **Compliance of well permitting programs with this requirement should be stated in the GSP.**

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 3.3.1 Geology and Hydrogeology (p. 3-7 to 3-9)]

- *[The GSA's response states: "Additional data is needed and will be addressed as a data gap when implementing the GSP." However, this data gap is neither described in the GSP nor filled by proposed monitoring plans.]* The GSP describes two principal aquifers on p. 3-9, the shallow aquifer and deeper aquifer. The GSP describes a strong connection between the two aquifers in portions of the Basin, with confinement or artesian conditions in other areas of the Basin. The GSP also describes springs and seeps on p. 3-14. However, the GSP does not clearly describe the hydrologic dynamics between surface expressions of groundwater (springs and seeps) and the two principle aquifers. The basin-wide cross sections provided in Figures 3-5a & 3-5b are regional and do not include a graphical representation of the manner in which shallow groundwater may interact with GDEs, nor does the HCM shown on Figure 3-3. **Please include further description and/or an example near-surface cross section that depicts the conceptual understanding of hydrologic dynamics that govern communication between the principal aquifers and surface expressions of groundwater.**
- *[The GSA's response states: "Additional data is needed and will be addressed as a data gap when implementing the GSP." However, this data gap is neither described in the GSP nor filled by proposed monitoring plans.]* The GSP states (p. 3-8): "For the GSP, the groundwater depletion that is of concern in the IWVGB is from the water in unconsolidated alluvial deposits. These water-bearing sediments store and transmit water and are divided into the following hydrostratigraphic features that are important for analyzing sustainability criteria and groundwater budgets." **Please include a discussion of the basin bottom in this section.** As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.

Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)

[Section 3.3.3.2 Streamflow and Mountain Front Recharge (p. 3-12 to 3-14)]
[Section 3.4.6 Interconnected Surface Water Systems (p. 3-34)]
[Section 4.3.5 Depletions of Interconnected Surface Water Undesirable Results (p. 4-15)]

- *[The GSA's response states "Comment addressed in Sections 4.3 and 4.3.5. Additional data is needed and will be addressed as a data gap when implementing the GSP. The IWVGA will reevaluate the need to establish sustainability criteria for interconnected surfaced water and GDEs as data gaps are filled." Thank you for acknowledging the importance of filling this data gap with future monitoring. However, please see our below recommendations for further analysis of ISWs which* *would help define specific future monitoring needs.]* The GSP states (p. 3-14): "There are no significant interconnected surface water systems which interact with groundwater in IWVGB" and goes on to state (p. 3-33): "Streams in the valley are typically ephemeral and the majority of recharge occurs as mountain front recharge. Additionally, there are multiple natural springs in the mountain and canyon areas surrounding the IWV (see Figure 3-11)." However, p. 4-15 states: "Groundwater is critical to sustaining springs, wetlands, and perennial flow (baseflow) in streams as well as to sustaining vegetation such as phreatophytes that directly tap groundwater." The GSP dismisses ISWs due to the ephemeral nature of streams in the valley, yet as noted above in the comments for Checklist Items 5-7, there is very little description of the interaction between principle aquifers and surface expression of groundwater. Without further documented evidence, ISWs should be retained for the consideration of sustainable management criteria. **This section of the GSP could be improved by providing further analysis of ISWs. Please note the following best practices for analyzing ISWs provided in the subsequent bullets.**

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface Digital Elevation Model that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. **Please evaluate stream reaches with depth to groundwater contour maps (please see Attachment D for best practices for completing this step). Please reconcile any data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features in the Monitoring Network section of the GSP to improve ISW mapping.**
- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. **Please provide a cross-section and/or corresponding hydrographs to show the relationship between the stream channels and the depth to groundwater at wells near the stream.**

<u>Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)</u>

[Section 3.4.7 Groundwater-Dependent Ecosystems (GDEs) (p. 3-35)]

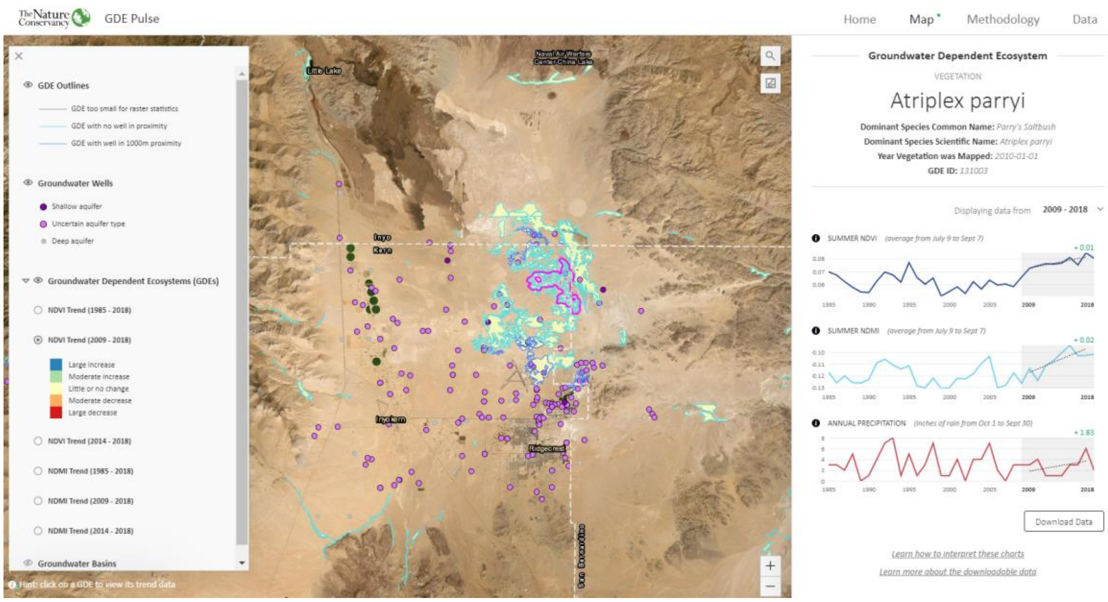
- *[No response required.]* TNC acknowledges and applauds IWVGA for the use of the NC dataset, as mapped on Figure 3-16. We also appreciate the inclusion of species type on Figure 3-16. The following suggestions could be used to clarify the analysis of the presence of potential GDEs in the Basin.

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* The NC dataset is a starting point for GSAs to identify GDEs in their basin. **Please map the original NC dataset, and clearly document which polygons were added (and what local sources were used to identify them), removed (and the removal reason), and kept (from the original NC dataset)**. The basin's GDE shapefile, which is submitted via the SGMA Portal, should also include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were added or removed). **Please clarify what the legend on Figure 3-16 means by "Not Applicable". If this represents a removed GDE Unit, please state the removal reason.**
- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* **Please provide one map to denote the most accurate picture of potential GDEs in the Basin showing the source of the data. For example, please note if any GDEs were added or removed based on the November 2018 field visit. Additionally, note if any GDEs were added or removed based on the US Navy mapping of GDEs on NAWS China Lake.**
- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* **On the final map figure, please use more easily distinguishable colors or patterns to distinguish the GDE Units from one another.**

<u>Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)</u>

[Section 3.4.7 Groundwater-Dependent Ecosystems (GDEs) (p. 3-35)]

- *[A reference to GDE Pulse was added to the GSP text. Thank you for citing TNC's resource for information on GDE health and groundwater conditions. The GSP could be further improved by adding further information from GDE Pulse, such as figures or text describing how this tool can be used for further analysis of GDEs over the GSP implementation period.]* **Please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present**. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the Indian Wells Valley Basin:



- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* **Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat are located in or near any of the GDEs, since some organisms rely on uplands and wetlands during different stages of their lifecycle**. Resources for this include the list of freshwater species located in the Indian Wells Valley Basin that can be found in Attachment C of this letter, the Critical Species Lookbook, and CDFW's CNDDB database. For example, please note where the endangered Mohave Tui Chub are located in reference to the GDE units.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 3.3.4 Water Budget and Overdraft Conditions (p. 3-15 to 3-25)]

- *[The GSA's response addresses our comment and appropriate GSP text changes were made. Thank you for clarifying outflow terms in the water budget.]* The GSP states (p. 3-20): "DRI performed a hydraulic analysis of the Salt Wells Valley and concluded that it is possible that currently approximately 50 AFY of the groundwater flow in the Salt Wells Valley originates as underflow from the IWV as distinguished from mountain front recharge from the Argus Range." The historical average budget in Table 3-6 shows the interbasin outflow as 60 AFY, while in the current budget in Table 3-7 the interbasin outflow is 50 AFY. **Please clarify the basis for the estimated amounts of interbasin outflow in the historical and current water budgets.**
- *[The GSA's response addresses our comment and appropriate GSP text changes were made. Thank you for clarifying how ET was calculated in the water budget.]* The current estimate of evapotranspiration (ET) in the basin is given as 4,850 ac-ft/yr (Table 3-7). The ET of saltgrass, pickleweed, greasewood and bare playa are discussed individually, but the basis of the total estimated evapotranspiration is not

provided. **Please clarify how the total ET was calculated in the current water budget.**

- *[The GSA's response addresses our comment and appropriate GSP text changes were made. Thank you for clarifying which water budget is baseline without the projects and management actions.]* The projected water budgets were simulated for the years 2035, 2040, and 2070 using the IWV groundwater model (Pohlman et al, 2019) with the projects and management actions implemented. The future budgets are shown in Table 3-8 with a new term Artificial Recharge included, representing the recharge by the projects and management actions. **In addition to the Predicted Water Budgets with Projects shown, please provide a baseline future budget without the projects and management actions.**
- *[The GSA's response: "See Section 3.5.6" does not address our comment and no changes to the GSP text were made.]* It appears that climate change was not considered in the projected water budgets. The GSP states (p. 3-48): "DRI (McGraw et al, 2016) examined the predicted precipitation quantities for several published IPCC climate models and documented conflicting results; ie, some models predicted decreases and some predicted increases in precipitation in the future with the assumed driver of CO2 increase. This GSP does not incorporate any precipitation change in model simulations into the future other than annual fluctuations similar to those that have been observed in the past record." The regulations [23 CCR §354.18(e)] state that "Each Plan shall rely on the best available information and best available science to quantify the water budget for the basin in order to provide an understanding of historical and projected hydrology, water demand, water supply, land use, population, climate change, sea level rise, groundwater and surface water interaction, and subsurface groundwater flow" (p. 12 of DWR BMP for Water Budgets[2]). DWR's Guidance for Climate Change Data[3] is intended as a source of guidance for climate change factors. **Please further elaborate on the decision to not consider climate change in the projected water budget considering the regulations and DWR guidance. Please further describe the methodology for future precipitation that was employed.**

Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)

[Section 4.2 Sustainability Goal (p. 4-2)]

- *[The GSA's response states: "Comment noted. Environmental beneficial uses and users are recognized as part of the community." GSP text changes were not made however.]* The GSP states the Sustainability Goal as (p. 4-3): "The sustainability goal is to manage and preserve the IWVGB groundwater resource as a sustainable water supply. To the greatest extent possible, the goal is to preserve the character of the community, preserve the quality of life of IWV residents, and sustain the mission at

---

[2] DWR Best Management Practice for Water Budgets. https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents

[3] DWR Guidance for Climate Change Data Use During GSP Development: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Sustainable-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents/Files/Climate-Change-Guidance-Final_ay_19.pdf

NAWS China Lake." There is no mention of environmental users or uses (GDEs and ISWs) in the Sustainability Goal. **Since GDEs are present in the Subbasin, they should be recognized as beneficial users of groundwater and should be included in the Sustainability Goal.**

Checklist Items 26-29 – Measurable Objectives (23 CCR §354.30) and Minimum Thresholds (23 CCR §354.28)

[Sections 4.4.2 Chronic Lowering of Groundwater Levels Minimum Threshold (p. 4-19)]
[Sections 4.5.2 Chronic Lowering of Groundwater Levels Measurable Objective and Interim Milestones (p. 4-32)]

- *[The GSA's response states: "Revisions made to Section 4.3 and Section 4.3.5." However, these revisions only state that IWVGA will reevaluate the need to establish sustainability criteria for interconnected surfaced water and GDEs as data gaps are filled. The plan proposes further reductions in groundwater storage and water levels until projects can alleviate further water groundwater overdrafting. This may well cause the reduction or elimination of groundwater dependent ecosystems. This issue must be analyzed and addressed in the plan.*] This Minimum Threshold and Measurable Objective do not consider GDEs. Because GDEs rely on shallow groundwater, further groundwater monitoring in the shallow zone is necessary to determine potential effects on GDEs. The representative monitoring sites for chronic lowering of groundwater level SMC are wells that monitor the deeper aquifer and thus do not monitor potential effects on GDEs. **Please include GDEs in these sections and state whether the minimum thresholds, measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.4.3 Degraded Water Quality Minimum Threshold (p. 4-24)]
[Sections 4.5.3 Degraded Water Quality Measurable Objective and Interim Milestones (p. 4-32)]

- *[The GSA's response states: "Revisions made to Section 4.3 and Section 4.3.5." However, these revisions only state that IWVGA will reevaluate the need to establish sustainability criteria for interconnected surfaced water and GDEs as data gaps are filled. Our comment was not addressed.]* This Minimum Threshold and Measurable Objective do not consider the water quality needs of GDEs. As previously stated, because GDEs rely on shallow groundwater, further groundwater monitoring in the shallow zone is necessary to determine potential effects on GDEs. The representative monitoring sites for degraded water quality SMC are wells that monitor the deeper aquifer and thus do not monitor potential effects on GDEs. **Please include a discussion about GDEs and water quality and state whether the minimum thresholds, measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to environmental users and uses of groundwater.**

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 4.3.2 Chronic Lowering of Groundwater Levels Undesirable Results (p. 4-11)]

- *[The GSA's response states: "Revisions made to Section 4.3 and Section 4.3.5." However, these revisions only state that IWVGA will reevaluate the need to establish sustainability criteria for interconnected surfaced water and GDEs as data gaps are filled. Our comment was not addressed.]* This section only describes potential effects relating to human beneficial uses of groundwater and neglects environmental beneficial uses that could be adversely affected by chronic groundwater level decline. **Please add "potential adverse impacts to environmental uses and users" to the list of potential effects presented in Section 4.3.2.3.**
- *[The GSA's response states: "Additional data is needed and will be addressed as a data gap when implementing the GSP." However, this data gap is neither adequately described in the GSP nor filled by proposed monitoring plans.]* This section refers to the shallow well impact analysis in Appendix 3E and states that the number of shallow wells that would be impacted if the proposed projects and management actions are implemented is estimated to be 22, which IWVGA considers a feasible number of wells that can be mitigated. GDEs, however, are not considered in this analysis. Damage to GDEs can occur within a relatively short period of time and can be irreversible, leading to the permanent loss of an environmental resource. **Please elaborate on how the criteria for determining Undesirable Results would be applied in a way that is protective of significant and unreasonable harm to GDEs. A triggering procedure could be included for violation of minimum thresholds that includes early identification of potential GDE impacts and appropriate response actions. This could be accomplished efficiently and cost-effectively using remote sensing tools, such as GDE Pulse. Refer to Appendix E of this letter for an overview of GDE Pulse, an online tool for monitoring the health of GDEs over time.**
- *[The GSA's response states: "Additional data is needed and will be addressed as a data gap when implementing the GSP." However, this data gap is neither adequately described in the GSP nor filled by proposed monitoring plans.]* **Please provide more specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs.** The definition of 'significant and unreasonable' is a qualitative statement that is used to describe when undesirable results would occur in the basin, such that a minimum threshold can be quantified. Potential effects on all beneficial users of groundwater in the basin need to be taken into consideration. According to the California Constitution Article X, §2, water resources in California must be "put to beneficial use to the fullest extent of which they are capable". **Please identify appropriate biological indicators that can be used to monitor potential impacts to environmental beneficial users due to groundwater conditions. Refer to Appendix E of this letter for an overview of GDE Pulse, an online tool for monitoring the health of GDEs over time.**

[Section 4.3.3 Degraded Water Quality Undesirable Results (p. 4-12)]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* This section only describes potential effects relating to human beneficial uses of groundwater and neglects environmental beneficial uses that could be adversely affected by degraded water quality. **Please add "potential adverse impacts to environmental uses and users" to the list of potential effects presented in Section 4.3.3.3.**

[Section 4.3.5 Depletions of Interconnected Surface Water Undesirable Results (p. 4-14)]

- *[The GSA's response is: "Revisions made to Section 4.3 and Section 4.3.5. The IWVGA will reevaluate the need to establish sustainability criteria for interconnected surfaced water and GDEs as data gaps are filled." Very little analysis of ISWs is provided in the GSP, nor are data gaps or plans to fill them adequately described. Our comment was not addressed.]* GDEs are often adjacent to streams or associated with riparian corridors where ISWs exist, even if only seasonally or are discontinuous along a longitudinal profile. ISWs that are not continuously connected spatially and/or temporally are still ISWs and should not be excluded from this GSP. The regulations [23 CCR §351(o)] define interconnected surface waters as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". **Please include ISWs in the Sustainable Management Criteria and state how they will help achieve the Sustainability Goal as it pertains to the environment.**
- *[The GSA's response is: "Revisions made to Section 4.3 and Section 4.3.5." However, these revisions only state that IWVGA will reevaluate the need to establish sustainability criteria for interconnected surfaced water and GDEs as data gaps are filled. Please include further analysis for potential depletion of ISWs. It is critically important that the plan include steps to determine whether regional springs could be affected by reductions in groundwater levels.]* The GSP states (p. 4-15): "Groundwater is critical to sustaining springs, wetlands, and perennial flow (baseflow) in streams as well as to sustaining vegetation such as phreatophytes that directly tap groundwater." It further states (p. 4-15): "Due to limited data on the relationship of interconnected surface water (springs) to GDEs and GDE's direct use of groundwater, no additional sustainable management criteria are proposed at this time." This section does not consider Undesirable Results for Interconnected Surface Water systems. **Even though data is lacking on ISWs, they should be included in the Sustainable Management Criteria and Undesirable Results. The analysis for potential depletion of ISWs should include beneficial users of surface water that could be affected by groundwater withdrawals, including environmental users. Please discuss the data gap for ISWs in the Monitoring Network section of the GSP and discuss future plans to fill the data gap. Possible monitoring could include shallow monitoring wells, stream gauges, and nested/clustered wells along surface water features to improve ISW mapping.**

<u>Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)</u>

[Section 4.7.1 Proposed Monitoring Network and Schedule (p. 4-36 to 4-37)]

- *[The GSA's response states: "Comment noted. See Section 3.6.1.4 and 4.3.5. Additional data is needed and will be addressed as a data gap when implementing the GSP." However very little description is provided in these sections. Please further elaborate on the GDE monitoring program.]* The GSP states (p. 4-15): "Specifics regarding the relationship between groundwater levels and the health of GDEs is currently not known, including extinction root depths, and there is no current monitoring program to track GDE health; therefore, GDE monitoring, currently a data gap, is proposed as part of the GSP monitoring program." However, this monitoring is not described in Section 4.7. **Please describe the GDE monitoring program and address how the need to link and correlate groundwater level declines to biological responses and significant and adverse impacts to GDEs and ISWs will be addressed by the monitoring program.**
- *[This comment was omitted from the response to comments document. No GSP text changes were made.]* Section 4.7.1 states that wells to monitor water levels near the GDEs will be added to the monitoring program, however no further details are provided. **For adequate characterization of groundwater conditions near GDE Units, please provide a detailed plan for filling this data gap. Please propose the locations of wells near GDE Units, the screened interval, and the schedule for installation.**
- *[The GSA's response states: "Additional data is needed and will be addressed as a data gap when implementing the GSP." However, this data gap is neither adequately described in the GSP nor filled by proposed monitoring plans.]* The GSP states (p. 3-50): "Data gaps in the groundwater level monitoring program exist outside of the pumping areas. There are only a few monitoring wells in the El Paso area, mostly open space managed by BLM. Groundwater resources in this area have not been fully characterized or quantified. The largest ephemeral stream system in IWV commences from this area in Freeman and Little Dixie Washes. Additional well drilling to characterize the aquifer structure and properties, and groundwater level monitoring could provide a better understanding of the occurrence and movement of water in this area." **Please discuss this data gap in the Monitoring Network section of the GSP and discuss future plans to fill this data gap. Possible monitoring could include shallow monitoring wells, stream gauges, and nested/clustered wells along surface water features to improve ISW mapping.**
- *[The GSA's response states: "Additional data is needed and will be addressed as a data gap when implementing the GSP." However, this data gap is neither adequately described in the GSP nor filled by proposed monitoring plans.]* The GSP states (p. 4-36): "The existing groundwater level monitoring network is very robust for establishing changes in groundwater levels over time throughout the Indian Wells Valley basin and will continue throughout the planning horizon. As discussed in Section 3.6, depth to water is, and will continue to be, measured biannually at 198 wells during Spring (March) and Fall (October) to observe seasonal changes in groundwater levels. Water levels measured at these wells will also be used to determine the change of storage in the Basin annually." The ten proposed representative wells to be used for monitoring groundwater levels, shown in Figure

4-2 and listed in Table 4-1, are predominantly deep wells which will not adequately monitor impacts to GDEs. **Please expand the shallow groundwater monitoring network through shallow and/or nested wells to further understand the potential for GDEs to be supported by shallow groundwater or upward vertical gradients that produce surface expression of groundwater in the form of springs and seeps. If existing wells cannot be used to monitor the shallow aquifer, propose installing new wells.**

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* The GSP states (p. 3-49): "Ten multi-level monitoring wells provide vertical gradients of groundwater flow, identifying some of the recharge and discharge areas within the Basin." **Please show the location of these wells on a map and present the well hydrographs, along with an analysis of the vertical gradients that can be determined from the data.**

Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Section 5. Projects and Management Actions (p. 5-1)]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* We appreciate that the IWVGB includes GDEs that are beneficial environmental uses and users of groundwater. To strengthen management of environmental beneficial users and uses, they should be considered in establishing project priorities. In addition, consistent with existing grant and funding guidelines for SGMA-related work, consideration should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities. For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* Recharge basins, reservoirs and facilities for managed stormwater recharge projects can be designed as multi-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such multiple-benefit projects and facilities have been incorporated into local Habitat Conservation Plans (HCPs) and Natural Community Conservation Plans (NCCPs), more fully recognizing the value of the habitat that they provide and the species they support. **For projects that construct recharge basins, please consider identifying if there is habitat value incorporated into the design and how the recharge basins could be managed to benefit environmental users**. Grant and funding priorities for SGMA-related work may be given to multi-benefit projects that can address water quantity as well as provide environmental benefits. **Therefore, please include environmental benefits and multiple benefits as criteria for assessing project priorities.**

- *[No response needed.]* For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

[Section 5.2.1 Management Action No. 1: Implement Annual Pumping Allocation Plan, Transient Pool and Fallowing Program (p. 5-4 to 5-13)]

- *[The GSA's response: "Revisions made to Section 4.3 and Section 4.3.5" does not address our comment and no changes to the GSP text were made.]* The IWVGA proposes an Annual Allocation Plan, Transient Pool and Fallowing Program to address the critical overdraft in the Basin. "The IWVB does not have the legal authority to restrict, assess, or regulate production for NAWS China Lake, therefore NAWS China Lake groundwater production is considered highest of beneficial use" (p. 5-10). "Implementation of the Annual Pumping Allocation Plan, Transient Pool and Fallowing Program may be subject to environmental regulations and could require the preparation of environmental studies. The IWVGA will follow all regulatory requirements associated with the environmental processes including public noticing and review requirements" (p. 5-11). **Please include environmental users in the list of beneficial uses of groundwater on p. 5-10 and describe how GDEs will be protected after this management action is implemented.**

[Section 5.3.1 Project No. 1 Develop Imported Water Supply (p. 5-13 to 5-22)]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made. Given the scarcity of available surface water supplies, please also include an analysis of the impacts on groundwater dependent ecosystems pending acquisition of water imports, given accompanying reduction in groundwater storage and lowering of water levels.]* The IWVGA is considering two options for importing water into the Basin, thereby reducing reliance on groundwater. Project benefits include increasing groundwater levels and groundwater storage, improved water quality, and reduced land subsidence, however there is no mention of potential environmental benefits. **Please state what environmental benefits or detriments would accrue from this project.**

[Section 5.3.2 Project No. 2 Optimize Use of Recycled Water (p. 5-23 to 5-33)]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* Two projects have been proposed to increase the quantity of recycled water at the City of Ridgefield treated wastewater and use it for landscaping at several locations shown in Figure 5-3 and 5-4. The purpose of these projects is to replace use of groundwater with use of non-potable recycled water, benefitting groundwater levels and storage. However, the recycled water currently benefits the Tui Chub habitat. Increased use of recycled water for other purposes would decrease return flows that are a significant source of water for Tui Chub habitat. **Please describe how the habitat of the Tui Chub will be protected if this project is implemented.**

[Section 5.4.3 Additional Projects (p. 5-52)]

- *[The GSA's response "Comment noted" does not address our comment and no changes to the GSP text were made.]* The GSP states (5-52): "The IWVGA is taking an adaptive management approach to IWVGB management over the planning horizon. Consequently, potential projects and management actions will continuously be considered and evaluated over the planning horizon to ensure that the most beneficial and economically feasible projects and management actions are implemented to reach sustainability in the IWVGB." **Please discuss the protection of environmental users and environmental benefits in the evaluation process.**

Attachment C

Freshwater Species Located in the Indian Wells Valley Basin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Indian Wells Valley Basin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[4]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[5] as well as on TNC's science website[6].

Scientific Name	Common Name	Legally Protected Species		
		Federal	State	Other
Birds				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	Bird of Conservation Concern	Special Concern	BSSC - First priority

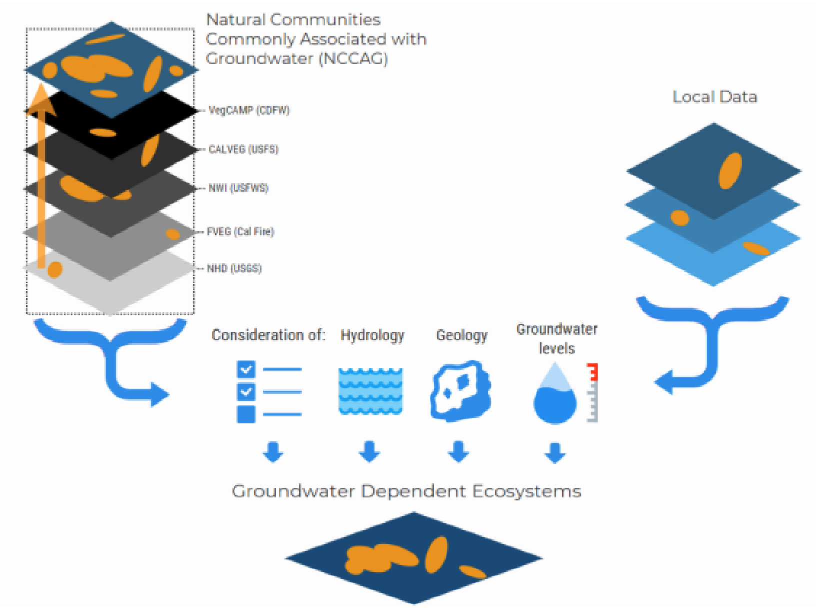
IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[7] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[8]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48

[7] NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/

[8] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[9]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[10] on the Groundwater Resource Hub[11], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

[11] The Groundwater Resource Hub: www.GroundwaterResourceHub.org

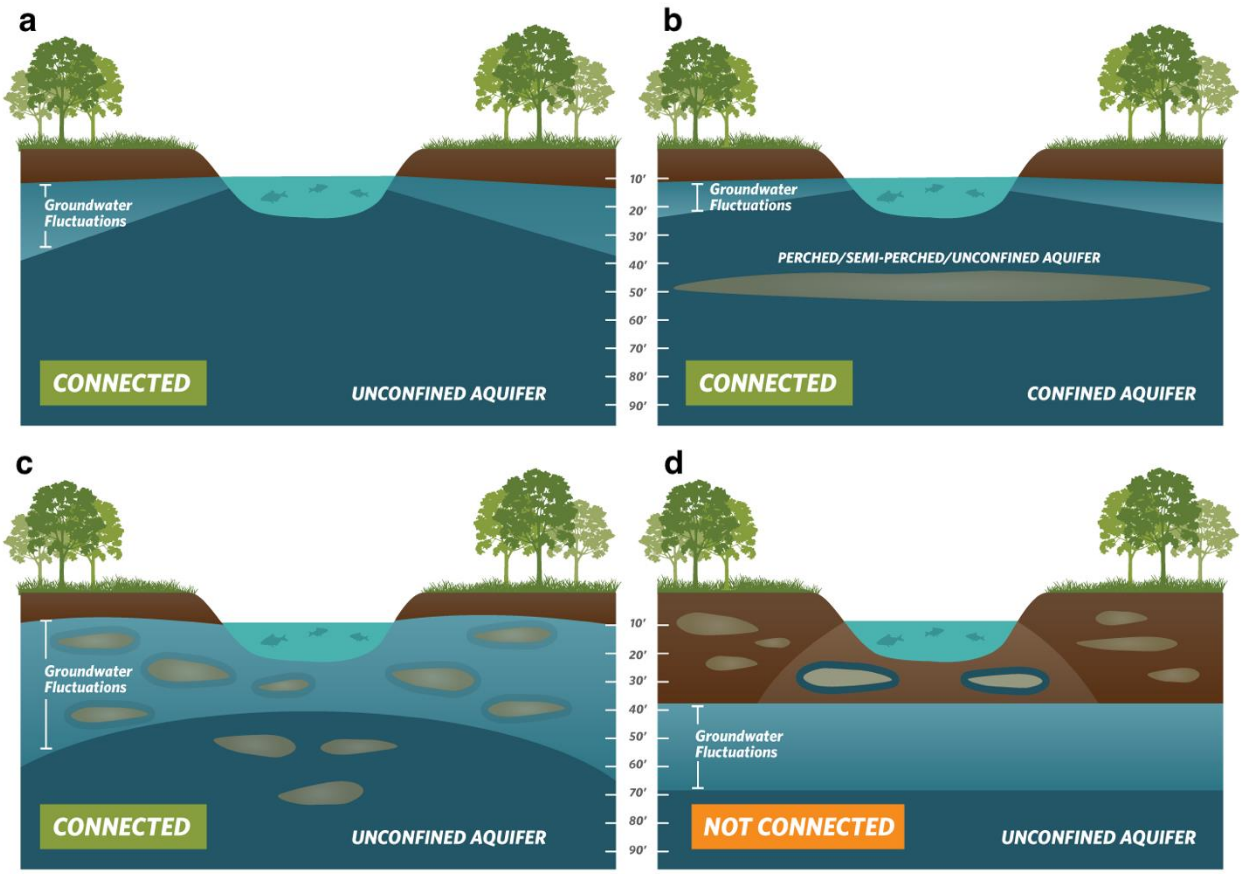

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[12] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[13] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[14] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[15]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

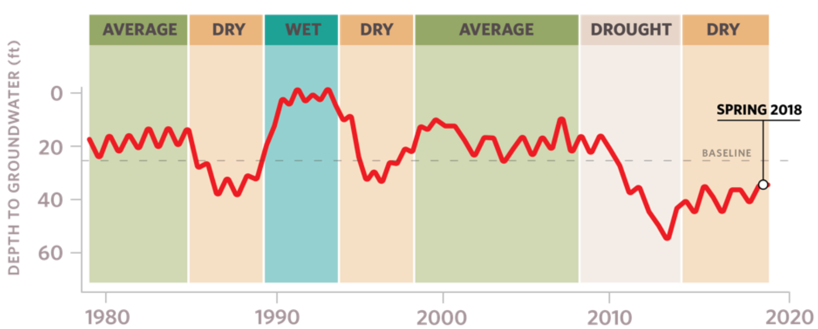

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

---

[12] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[13] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[14] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[15] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[16], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

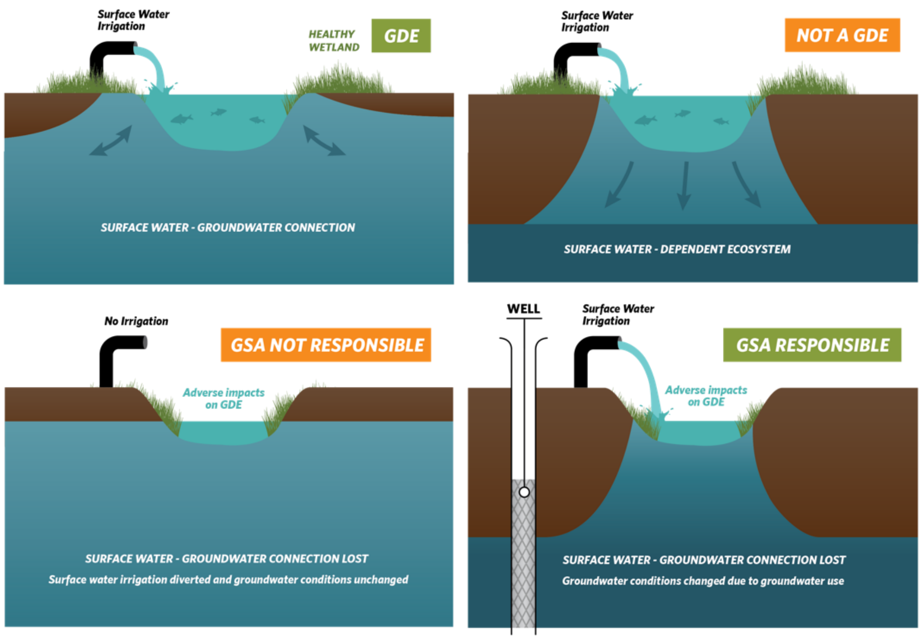

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[16] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

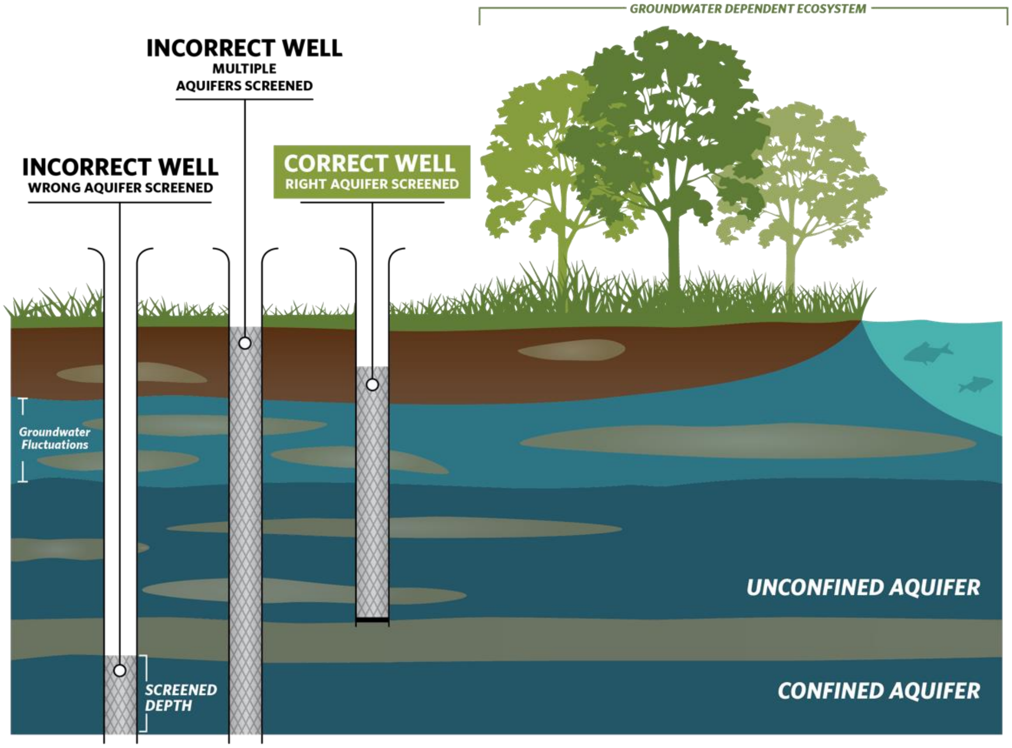

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[17] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

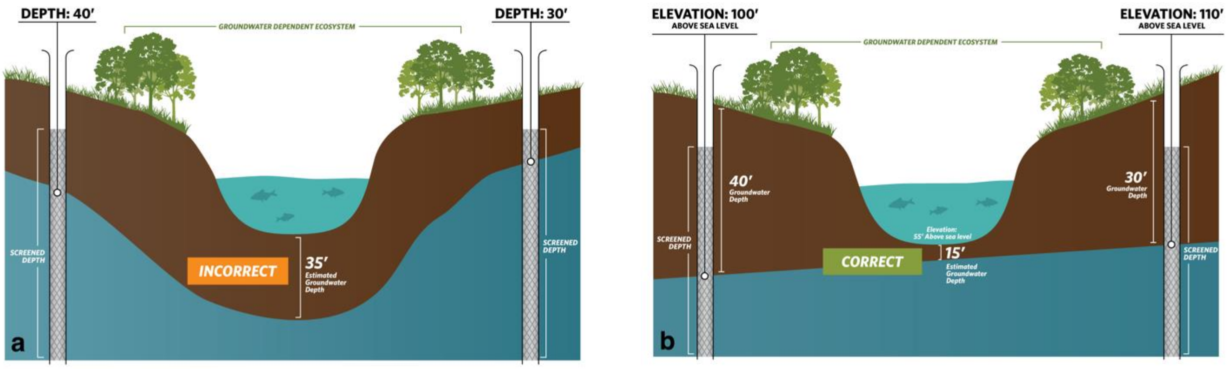

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

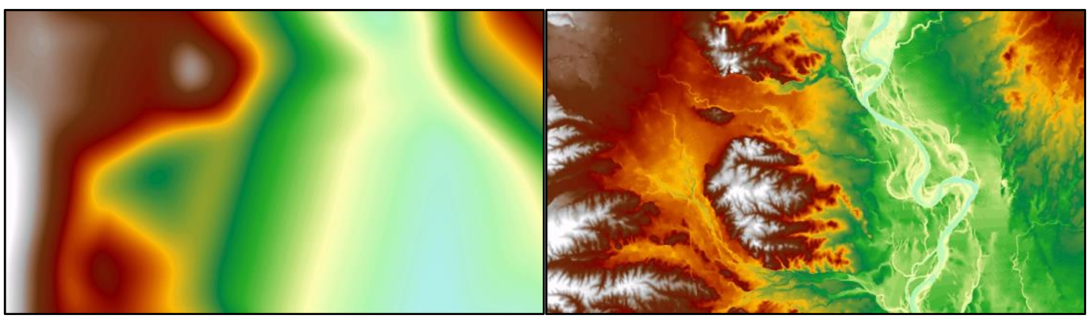

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[17] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

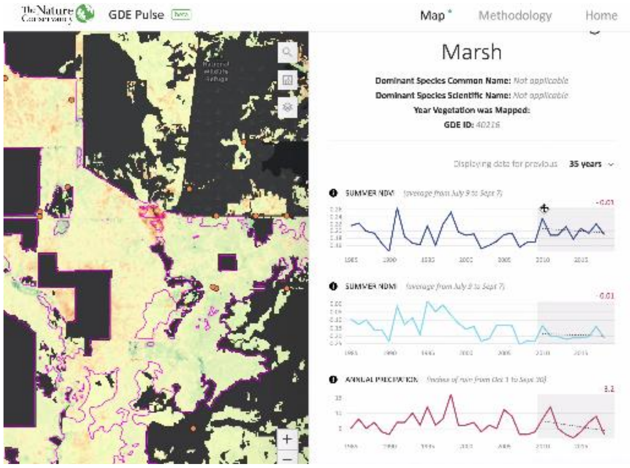
Attachment E

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[18]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[19]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Attachment F

The GSA Response to TNC Comments on the Draft GSP is located on the DWR SGMA portal as Part 2 of 2 of our comments.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[20]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[21]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[22] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Kern Groundwater Authority Groundwater Sustainability Plan (GSP)

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Kern Groundwater Authority (KGA) Groundwater Sustainability Agency's (GSA's) Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users. The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some case, it may be difficult to address gaps within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users indicate the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of potential ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as only 1 out of 37 comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

TNC recommendation: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters - The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP excluded potential ISWs without providing comprehensive monitoring data and quantitative analysis. The data provided in the GSP to substantiate the claims only cover portions of the surface water system. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)).

Map and Assessment of potential ISWs:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy's assessment found that within portions of Kern Groundwater Authority GSP where sufficient data exist, 16.3 river miles are gaining, 1.7 are losing, and the rest are uncertain, likely disconnected, or have insufficient groundwater depth data to classify connection. Importantly, TNC's analysis excludes large portions of the plan area, where most of the potential ISWs are found, which reinforces the need to assess groundwater-surface water connections in the GSP. Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs and prioritize the installation of additional shallow wells at locations near high value or sensitive resources that are vulnerable to significant and unreasonable adverse impacts. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 44,294 acres of potential GDEs occur in the GSA boundary. TNC developed the Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

While we were pleased to see that the GSP took some steps to identify and map GDEs, we found that some GDEs were improperly disregarded. We recommend that the GSP remedy the omissions by following our recommendations in Attachment B. The GSP should also revisit all components of the plan where GDEs, as a beneficial user, must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives. Our review found that NC Dataset polygons were improperly removed from the GDE map based on the following:

- GDEs were rejected on the basis that groundwater levels were greater than 30 feet at a single point in time. This is a technically incorrect approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30 feet or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unprotected in the GSP.

TNC recommendation: TNC recommends that DWR request the GSA to use groundwater levels that represent interannual and inter-seasonal variability and utilize additional information (Attachment D) which provides best practices for using the NC Dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use Digital Elevation Model (DEM) when developing depth to groundwater contours, as described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and/or managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). The GSP provides a summary of evapotranspiration (ET) for each land cover type but did not provide a breakdown of ET for native and riparian vegetation (such as wetlands, riparian vegetation, phreatophytes and other communities). This is problematic because key environmental uses of groundwater are not being accounted for as water supply decisions are made using this budget nor will they likely be considered in project and management actions.

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

TNC recommendation: As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

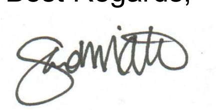
TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

The Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. The GSP does not include the description of a monitoring network to provide methodologies, data and other information to address the data gaps associated with GDEs and ISWs. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,



Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Attachment A

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Kern Groundwater Authority Groundwater Sustainability Plan

The complete Kern Groundwater Authority (KGA) Groundwater Sustainability Agency (GSA) Groundwater Sustainability Plan (GSP), adopted on January 15, 2020, was reviewed by TNC. Responses to comments received on the complete public draft GSP are provided as Attachment D of the Final GSP. The TNC comments and responses are also provided in Attachment F of this letter. This attachment lists our original comments on the complete public draft GSP, as submitted during the public comment period, and states whether or not they were addressed in the complete Final GSP *[as green text in brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 – Notice & Communication (23 CCR §354.10)

[Section 2.1.5.1 Description of Beneficial Uses and Users in the Basin (p. 38) and Section 2.2.1.4 Kern County Subbasin Boundaries, Criteria for the Extent of Groundwater with Beneficial Use in the Subbasin (p. 60)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* California Water Code §1305(f) defines beneficial uses of waters of the State as including "preservation and enhancement of fish, wildlife, and other aquatic resources and preserves." Section 2.1.5.1 states that beneficial users are stakeholders who have an interest in or need groundwater use. The discussion focuses on active groundwater pumpers but does not mention environmental uses or environmental stakeholders. Section 2.2.1.4 focuses on criteria for determination of groundwater with beneficial use for human consumption or mineral extraction, but omits references in the California Water Code to environmental beneficial uses. **Please describe the other beneficial uses and users of groundwater in the Subbasin identified by the Water Code including: GDEs; managed wetlands; Protected Lands, including preserves, wildlife refuges, conservation areas, recreational areas and other protected lands; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, recreation and navigation.**
- *[Minor changes to GSP text were made but did not adequately address the comment.]* The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses and users of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. **Please identify any environmental uses and users of groundwater in the plan area, and take particular note of the species with protected status.** The following are resources that can be used:
    - Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/;

- A list of freshwater species located in the Kern County Subbasin in Attachment C of this letter; and
- The California Department of Fish and Wildlife's California Natural Diversity Database (CNDDB).

Checklist Items 2 to 4 - Description of Plan Area (23 CCR §354.8)

[Section 2.1.2 Plan Area Setting (pp. 13-14)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GSP provides a description of the groundwater well types and well density; however, there is no discussion of instream flow requirements, if any, or how the water infrastructure is in compliance with regulatory requirements to protect species of concern in the surface waters within the Subbasin. **Please provide a description of any current and planned instream flow requirements or regulatory requirements for protection of species of concern in the Kern River, Poso Creek and Caliente Creek. If there are no requirements in place or planned, then please state that in the GSP.** Furthermore, while the response claims that Kern River is not within KGA, Figure 1-1 clearly shows that sections of the Kern River are within the boundary of KGA.

[Section 2.1.3 Existing Plans in the Plan Area (pp. 17-18)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* This section summarizes the Kern County General Plan and general plans for cities within the GSP area. The plan descriptions are focused on goals and policies directly related to groundwater resources and do not include policies and goals related to surface water resources that may be connected to groundwater. **We suggest adding a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. Please include a description of any land use or environmental plans relevant to wetlands, aquatic resources and other GDEs and ISWs and their relationship to the GSP. Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands around the Kern Wildlife Refuge, aquatic resources and other GDEs and ISWs.**
- *[Minor changes to GSP text were made but did not adequately address the comment.]* This section is focused on discussion of agriculture and irrigation needs, demands, and types of irrigation, and the groundwater resources policies and goals in general plans. It does not include any other applicable land use or environmental plans that may contain information relevant to the GSP and ISWs. This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**

[Section 2.1.4 Existing and Ongoing Water Resource Programs (pp. 29-31)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *and related surface conditions* (emphasis added). In order for this section to provide the appropriate context and help assure integration of GSP implementation with other ongoing regulatory programs, additional information on water use management and monitoring programs relevant to wetlands, sensitive or critical habitat, and GDEs and their relationship to the GSP should be provided.
  - **Please provide a description of resource management plans, monitoring activities and responsibilities by State, Federal and local agencies and jurisdictions related to aquatic resources and GDEs that could be affected by groundwater withdrawals, and list them in Table 2-1.**
  - The Critical Habitat for Threatened and Endangered Species website maintained by US Fish and Wildlife Service (https://fws.maps.arcgis.com/home/webmap/viewer.html?webmap=9d8de5e265ad4fe09893cf75b8dbfb77) identifies multiple lands with endangered and threatened species in the Subbasin, for instance, Buena Vista Lake Ornate Shrew (*Sorex ornatus relictus*) occurs within the area. **Please review and discuss the potential groundwater reliance of critical species in the Subbasin. Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**
  - Other GDEs and sensitive habitats. **Please include a discussion of any monitoring programs related to GDEs and sensitive habitats.**

[Section 2.1.4.3 Well Permitting Process (p. 34) and Section 2.1.4.4 Plan Elements from CWC Section 10727.4 (g) Well Construction Policies (p. 34-37)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* These sections discuss the Kern County Public Health Services Department Water Well Program, which issues permits to construct, reconstruct, and destroy water wells. The discussion does not provide any details regarding the potential effects of the permitting and construction of new wells on aquifer systems, GDEs and ISWs.
  - **Please discuss that future well permitting and well construction must be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**
  - **Please state how the well permitting process incorporates protection of GDEs and ISWs within the Subbasin.**
  - The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). **Please**

include a discussion of the need for well permitting programs to comply with this requirement.

Checklist Items 5 to 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 2.2.1.5 Bottom of Subbasin (p. 60)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The bottom boundary of the Subbasin should be more precisely defined in accordance with DWR guidance. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions." Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom. This will prevent the possibility of extractors with wells deeper than the basin boundary (defined by the base of freshwater) from claiming exemption of SGMA due to their well residing outside the vertical extent of the basin boundary. **Please characterize groundwater well extractions from the deepest wells in relation to defining the basin bottom**. If the bottom boundary of the Subbasin has not been clearly defined in certain management areas, **please identify this as a data gap and elaborate in the monitoring section how and where additional observations can be made to reconcile this data gap.**

[Section 2.2.1.6 Principal Aquifers and Aquitards (pp. 80-74)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GSP includes a relatively robust description of the geologically diverse aquifers in the Subbasin with differing zones of confined, semiconfined and unconfined groundwater conditions, in addition to "shallow zones" stated to be present locally in the northwestern and southern portions of the central Subbasin. The GSP states these are *"not a part of active groundwater extraction, but data are included in the groundwater conditions section of this report to evaluate changes over time."* On page 53, environmental users are identified as beneficial groundwater users of the primary aquifers in the Subbasin. Please note that a Principal Aquifer is defined in the GSP regulations as including *"aquifers or aquifer systems that store, transmit, and yield significant … quantities of groundwater to … springs, or surface water systems*" (23 CCR §351(aa). As such, if the shallow aquifer interacts with surface water systems or provides groundwater necessary to sustain GDEs or other environmental beneficial users, it should be considered a Principal Aquifer. No description, data or information is provided regarding the potential effect of groundwater extraction from groundwater production aquifers on the uppermost shallow aquifers and groundwater bearing zones, whether perched aquifers exist, and how the shallow aquifers or zones are connected to and interact with surface water and GDEs. **Please provide additional description of the shallow aquifers within the Subbasin including characteristics of interconnections with surface water and GDEs, vertical groundwater**

gradients, connections with underlying production aquifers, and the resulting potential interaction of groundwater pumping with ISWs and GDEs. Please state whether localized perched aquifers are present in the Subbasin. Describe any data gaps. The function and significance of the Shallow Aquifers that provide groundwater to ISWs and GDEs should be summarized in Table 2-3.

- *[Minor changes to GSP text were made but did not adequately address the comment.]* **Please describe whether the existence of Aquifer Exemptions has any bearing or implications related to environmental beneficial uses of groundwater.**

[Section 2.2.1.7 Data Gaps and Uncertainty (p. 74)]

- *[Our comment was not adequately addressed by KGA's response. No changes to GSP text made.]* **If data are not present to produce the information requested in the comment above, please clearly identify this as a data gap. Please elaborate in the monitoring section how and where additional observations are to be conducted in order to address this data gap.**

[Section 2.2.1.8 Cross Sections (pp. 74-84)]

- *[Our comment was not addressed. No changes to GSP text made.]* Regional basin-wide geologic cross sections are provided in Figures 2-19a through 2-19g. These cross-sections do not include a graphical representation of the manner in which the very shallow groundwater or perched water may interact with ISWs or GDEs that would allow the reader to understand this topic. **Please include near-surface cross sections or insets that depict the conceptual understanding of shallow groundwater and ISW interactions at different locations, including perched and regional aquifers and GDEs.**

[Section 2.3.1.1 Elevation and Flow Directions (pp. 98-105)]

- *[Our comment has been adequately addressed through GSP text changes. Thank you for identifying the data gap.]* This section states that the depth to groundwater in the Shallow Zone ranges from 5 to 25 feet. Inference is made that groundwater levels in the Shallow Zone is relatively constant and is typically perched on fine grained sedimentary units and likely disconnected from the productive aquifer system. No specific data or hydrogeologic analysis is provided to substantiate these important claims. **Please provide any available stratigraphic data, hydrograph data, pumping test data or other information to substantiate these claims. If the data are not available, please identify this as a data gap.**

<u>Checklist Items 8, 9 and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)</u>

[Section 2.3.5 Interconnected Surface Water Systems (pp. 134-142)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted." "At any point" has both a spatial and temporal component. Even short durations of interconnection between groundwater and surface water can be crucial for surface water flow and support of environmental users and uses of groundwater and surface water. ISWs can be either gaining or losing. The text states (p. 134) that *"Within the Subbasin, there are no interconnected natural surface water systems in monitored areas associated with the pumping zone of the regional aquifer system"* and *"Since the advent of groundwater pumping in the Subbasin and subsequent impoundment and regulation of flow of the Kern River, groundwater levels near the river are no longer connected with the river bed by a continuous saturated zone."* However, the data provided to substantiate these broad claims cover only portions of the surface water flow system. The models cited as substantiation were not constructed for the purpose of identifying potential ISWs and GDEs, but are regional models constructed for supply management. In fact, the text also states (p. 142) that the Kern River has gained flow during some years and the upper reach of the Kern River in the Subbasin has been identified as gaining. The connection between surface water and groundwater is mentioned as a data gap in Section 2.3.7.4 (p. 142). Furthermore, the depth to water in the shallow aquifer is quite shallow as discussed above (5 to 20 feet below ground surface), which strongly suggests that interaction between the shallow aquifer and surface water may be occurring. Because there are uncertainties in the hydraulic connection between rivers / streams and shallow groundwater, ISWs should not be disregarded in the GSP. The GSP regulations require reliance on the best available information and clear identification of data gaps when sufficient information is not available. **Please provide additional data or analysis to substantiate the nature of the hydrologic relationship between the shallow aquifer and production aquifers and ISWs. If data are not available to verify that such a connection does not exist, acknowledge where ISWs may exist and identify appropriate sustainable management criteria, monitoring networks and management actions for sustainable ISW management or to address data gaps. Data could include groundwater level data from shallow or nested monitoring wells, comparison of stream stages to groundwater levels, modeling information or additional gaging data. Please elaborate how and where additional observations (shallow monitoring wells, stream gauges, and nested / clustered wells) along surface water features can be used to address data gaps in the Monitoring Network section of the GSP to improve identification of ISWs rather than prematurely disregarding them in the GSP**. Furthermore, while KGA's response to our comments claims that Kern River is not within the jurisdiction of KGA, Figure 2-1 in KGA GSP and Figure 2-2 in KRGSA GSP clearly shows that sections of Kern River are within the jurisdictional area of KGA.

<u>Checklist Items 11 to 15 – Identifying and Mapping GDEs (23 CCR §354.16)</u>

[Section 2.3.6 Groundwater-Dependent Ecosystems (pp. 151-152)]

- *[No response is required for this comment.]* We applaud KGA for using the NCCAG database, developed through a collaboration between DWR, California Department of Fish and Wildlife (CDFW) and TNC, to identify potential GDEs, and then evaluate the NCCAG results to identify GDEs; however, the approach used is based on narrative analysis and quantitative data are not used. In addition, no determination is presented as to which NCCAG polygons represent GDEs. **Please refer to Attachment D of this letter for best practices in using groundwater data to verify whether NCCAGs are GDEs.**
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* The text states (p. 152): "*Groundwater potentiometric surfaces from Kern Fan Monitoring Reports (KCWA, 2016) indicate that underlying aquifers are not connected with stream channels. Some flow in the Kern River, as well as in Poso Creek and other mountain-front creeks, is likely to be sustained periodically by release of bank storage (surface water stored in stream banks), but the underlying groundwater is too deep to sustain flow in the valley floor.*" This contradicts the statements on page 142 that the Kern River has gained flow during some years and the upper reach of the Kern River in the Subbasin are identified as gaining. If there are insufficient groundwater level data in the upper aquifer where gaining reaches are located or where bank storage is inferred to occur, then the NCCAGs in these areas should be included as GDEs in the GSP until data gaps are reconciled in the monitoring network. **Please identify any data gaps related to identifying and mapping GDEs. If there are data gaps, please describe in detail in the monitoring plan how the data gaps will be addressed.**
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* The text states (p. 152): "*The conditions in the center of the Subbasin suggest that the groundwater production aquifer does not reach the shallow subsurface. The production aquifer lies at depths that prevent surface water expressions or accessibility for vegetation.*" **Please support this statement with specific groundwater level data that indicate a gap in the saturated zone between the production aquifers and shallow groundwater, and define the extent of the NCCAG dataset polygons that are excluded from consideration as GDEs on this basis.**
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* The text states (p. 152): "Based on the NCCAG dataset along the margins of the Subbasin where spring-fed streams exist, further confirmation is needed to evaluate the presence of GDEs." If there are insufficient groundwater level data in the upper aquifer where these stream-fed springs exist, then the NCCAGs in these areas should be included as GDEs in the GSP until data gaps are reconciled in the monitoring network. **Please identify any data gaps related to identifying and mapping GDEs. If there are data gaps, please describe in detail in the monitoring plan how the data gap will be resolved.**
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* Because data gaps have been identified in Section 2.2.1.7 (p. 74) Section 2.3.7.4 (p. 142) and Section 2.3.8.2 (p. 152) related to shallow groundwater conditions and the identification of ISWs and GDEs within the Subbasin, final determination of the extent of GDEs in the Subbasin has yet to be completed.

Please revise the GDE analysis in the GSP by conducting more substantial, data-based evaluation focusing on GDE identification in the GSP, clearly identify which NCCAG polygons are excluded, which polygons are determined to be GDEs and which polygons are uncertain at this time and will be verified as data gaps are address. SGMA defines GDEs as "ecological communities and species that depend on *groundwater emerging from aquifers or on groundwater occurring near the ground surface*" (emphasis added). **Confirmation of GDEs should be performed based on depth to groundwater in the shallow zone, and additional information provided as to whether the shallow zone may be affected by groundwater withdrawal from the production aquifers. Please refer to Appendix D of this letter for best practices for using groundwater data to verify a connection to groundwater.**

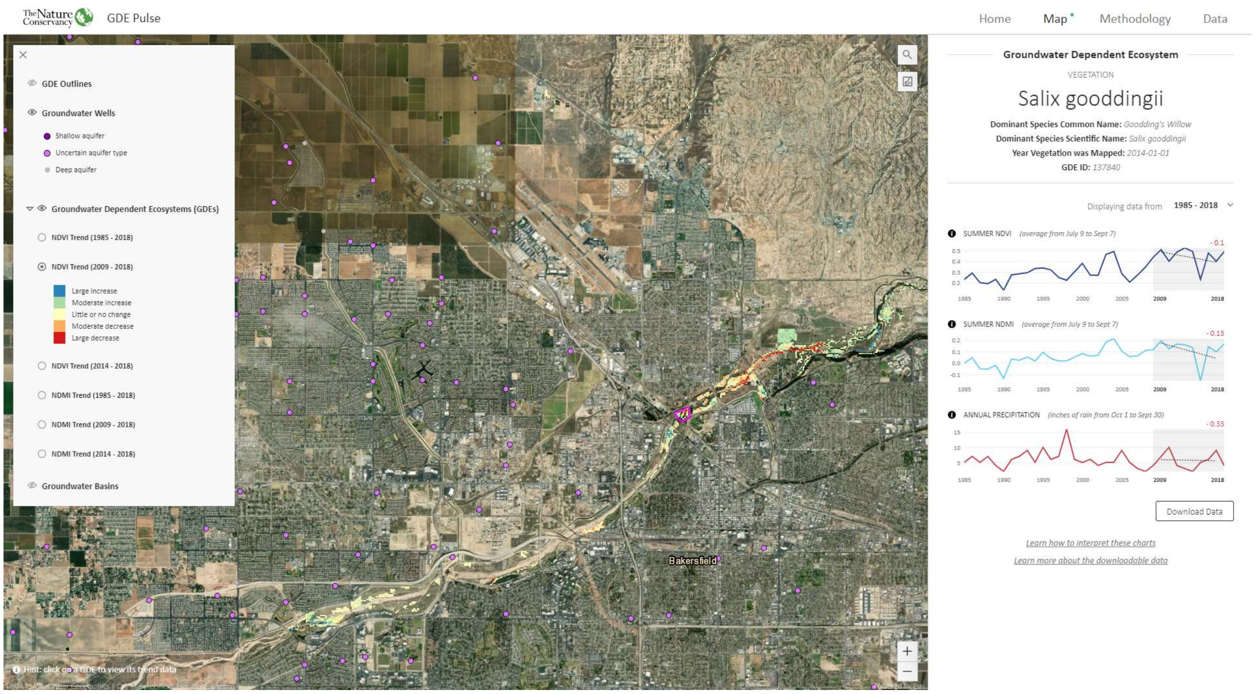
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* In the scientific literature, it is generally acknowledged that GDEs can rely on groundwater for *some or all* of their requirements (emphasis added). GDEs can rely on multiple water sources simultaneously and at different temporal and/or spatial scales (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow). SGMA defines GDEs as "ecological communities and species that depend on groundwater *emerging from aquifers* or on groundwater *occurring near* the ground surface" (emphasis added). **Therefore, we recommend using depth to groundwater contour maps derived from subtracting groundwater levels from a DEM, as described above, to identify whether a potential connection to groundwater exists for the wetlands mapped in Attachment H of the GSP. Please refer to Attachments D and E of this letter for best practices for using local groundwater data to 1) verify whether polygons in the NC Dataset are supported by groundwater in an aquifer, and 2) verify whether ecosystem decline or recovery is correlated with groundwater levels.**

Checklist Items 16 to 20 – Describing GDEs (23 CCR §354.16)

[Section 2.3.6 Groundwater-Dependent Ecosystems (pp. 151-152)]

- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* Very little description is provided regarding the nature and function of identified GDEs in the west-central and south-central portions of the Subbasin, their potential sensitivity to groundwater and surface water supply changes, or their relative habitat value. **We recommend the inclusion of a discussion regarding the nature and characteristics of GDEs.**
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* **Please provide information on the historical or current groundwater conditions near the GDEs or the ecological conditions present.** Refer to GDE Pulse (https://gde.codefornature.org or Attachment E of this document) or other locally available data (e.g. leaf area index, evapotranspiration or other data developed from remote sensing) and depth to groundwater trends in and

around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC Dataset polygons found in the Subbasin.



- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* **We recommend an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes vegetation or habitat types and rank the GDEs as having a high, moderate or low value. Explain how each rank was characterized.**
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* **Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found in or near any of the GDEs. Some organisms rely on uplands and wetlands during different stages of their lifecycle**. Resources for this include the list of freshwater species located in the Subbasin that can be found in Attachment C of this letter, the Critical Species Lookbook, and CDFW's CNDDB database.

Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)

[Section 2.4 Water Budget (p. 152)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GSP provides summary and refers to Attachment H for water budget information. In Attachment H, Section 3.7.1 discusses the development of evapotranspiration (ET) rates for each land cover type (p. 11). **Please provide a breakdown of ET for native and riparian vegetation (such as wetlands,**

riparian vegetation, phreatophytes and other communities). Please evaluate the spatial relationship of native vegetation ET to NCCAG polygons to determine the groundwater use by this beneficial user for inclusion in the water budget. Identify any data gaps and outline the actions needed to address them.

Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)

[Section 3.1 Sustainability Goal (p. 175)]

- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* The sustainability goal of the Kern County Subbasin is to *"Achieve sustainable groundwater management…Maintain its groundwater use within the sustainable yield of the basin…Operate within the established sustainable management criteria...maintain sustainability over the implementation and planning horizon."* The GSP regulations (23 CCR §354.24) require that *"[t]he Plan shall include a description of the sustainability goal, … a discussion of the measures that will be implemented to ensure that the basin will be operated within its sustainable yield, and an explanation of how the sustainability goal is likely to be achieved … and maintained … ."* The stated sustainability goal recites regulatory requirements and does not provide a description of the goal relative to the basin setting and beneficial uses. The goal does not mention environmental uses and users of groundwater and does not mention undesirable results. **Please clarify the sustainability goal and expand its description to ensure that all beneficial uses and users of groundwater are identified as being protected from undesirable results, and in particular, include GDEs, ISWs and related critical habitats**.
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* **Since GDEs and ISWs may be present in the Subbasin (please see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be specifically included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included.**
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* The GSP states that there is no ISW connectivity for the Kern River; however, there isn't any data, analysis and / or other information provided to support this broad conclusion. **Please include ISWs in the Sustainability Goal until/unless sufficient data is available and provided to verify the status of ISWs.**
- *[Our comment was not adequately addressed through the response. No changes to GSP text made.]* GDEs are dependent, in part, on suitable water quality; however, the GSP only considers water quality for irrigation and domestic use. **Given that there are potential GDEs in the Subbasin and that they may be affected by water quality, they should be included in the Sustainability Goal and addressed in the Water Quality section.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30) and Checklist Items 27 to 29 - Minimum Thresholds (23 CCR §354.28)

[Section 3.3 Minimum Thresholds and Measurable Objectives (pp. 181-195)]

- *[Our comment was not adequately addressed through the response. Minor changes to GSP text made.]* Minimum thresholds and measurable objectives for chronic lowering of groundwater levels, reduction of groundwater storage and degraded water quality do not include environmental beneficial users, such as ISWs or GDEs. **For each of these applicable sustainable management criteria, please include a discussion of GDEs (see comments under checklist items 16-20) and whether the minimum thresholds, measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment. Please modify Section 3.2.2 to specifically address impacts from degraded water quality to the plant and wildlife communities within GDEs.**

<u>Checklist Items 30 to 46 – Undesirable Results (23 CCR §354.26)</u>

[Section 3.2.2.2 Potential Effects of Chronic Lowering of Groundwater Levels (p. 177)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* GDEs are a beneficial user of groundwater in the Subbasin. **Unless evidence is provided to verify the exclusion of GDEs please modify this section of the GSP to identify GDEs as one of the beneficial uses and users of groundwater that could experience significant and unreasonable effects as a result of chronic lowering of groundwater levels.**

[Section 3.2.7 (Undesirable Results for depletion of) Interconnected Surface Water (p. 181)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GSP states (p.195) that *"Though many studies have been conducted in the Subbasin, including in areas such as the Kern River and Poso Creek, results do not show evidence of surface water within the Subbasin to be interconnected. As there are no known natural interconnected surface water systems within the KGA boundary, this sustainability indicator is not included in this GSP."* As noted in the prior comments, several areas have been identified as potential ISWs and GDEs, and substantial data gaps exist. As such, the above statement contradicts other information provided in the GSP, and serves as an acknowledgement of data gaps. It is not an appropriate basis for removing this sustainability indicator from the GSP under the GSP regulations. **Unless evidence is provided to verify the exclusion of GDEs and ISWs, please modify this section of the GSP to include a statement that 1) there are potential ISWs, and 2) provide an assessment of potential undesirable results.**
- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GSP states (p.144) that *"… there is no interconnected surface water under the influence of groundwater pumping in the principal aquifer in this area and no impacts to interconnected surface water have been observed."* As noted in the prior comments, areas of shallow groundwater and gaining stream reaches are known to exist in the Subbasin. No quantitative data have been provided to assess

the extent of hydraulic connection between shallow groundwater and the underlying production aquifers. As such, the above statement is insufficiently supported by data and is actually a substantial data gap. **Unless evidence is provided to verify the potential influence of groundwater extraction on GDEs and ISWs, please modify this section of the GSP to include a statement that the data are insufficient to assess whether GDEs can experience significant and unreasonable effects as a result of groundwater extraction in the Subbasin and provide an assessment of potential undesirable results. Please also identify that existing data gaps will be addressed and the presence or absence of GDEs will be verified with monitoring wells screened at the appropriate depths.**

[Section 3.2 Undesirable Results (for each sustainability indicator) (pp. 175-181)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses / users that could be adversely affected by chronic groundwater level decline or other undesirable results. **Please add "possible adverse impacts to potential GDEs and ISWs" to the list of potential undesirable results.**
- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GDE Pulse web application developed by TNC provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC Dataset polygons within the Subbasin. Over the past 10 years (2009-2018), some NC Dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture in the western portion of the Subbasin. **Please review these spatial patterns and, where possible, correlate them with water level trends. Any indications of adverse trends and any data gaps should be identified.**

  - **For each identifiable GDE unit with supporting hydrological datasets, please include the following:**
    - Plot and provide hydrological datasets;
    - Define the baseline period in the hydrologic data;
    - Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater; and
    - Explore cause-and-effect relationships between groundwater changes and GDEs.
  - **For identifiable GDE units without supporting hydrological datasets please describe data gaps and / or insufficiencies.**
  - **Compile and synthesize biological data for each GDE unit by:**
    - Describing biological resources for each GDE unit; and
    - Describing data gaps / insufficiencies.
  - **Describe possible effects on potential ISWs, GDEs, land uses, and property interests, including:**

  - Cause-and-effect relationships between potential ISWs and GDEs with groundwater conditions;
  - Impacts to potential ISWs and GDEs that are considered to be "significant and unreasonable;"
  - Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities;
  - Land uses should include recreational uses (e.g., fishing/hunting, hiking, boating); and
  - Property interests should include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.

<u>Checklist Items 47-49 – Monitoring Network (23 CCR §354.34)</u>

[Section 3.4 Monitoring Network (pp. 195-216)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GSP proposes to coordinate and use existing monitoring networks of Kern Groundwater Authority and its districts / member agencies for groundwater elevations and storage, groundwater quality, and land subsidence. The text (p. 197) states that the monitoring network will monitor impacts to the beneficial uses and users of groundwater and goes on to state that "*<u>depletions of interconnected surface water are not pertinent to the monitoring network</u>*."(emphasis added) As discussed in previous comments, unless data are provided to support this broad statement, due to uncertainties in the hydraulic connection between rivers / streams and GDEs with shallow groundwater, ISWs and related GDEs should not be disregarded in the GSP. The GSP should include a description of how groundwater conditions will be monitored to assess the potential effects of groundwater withdrawals on ISWs and GDEs. In addition, this section should include a description of how hydrological data gaps and insufficiencies will be addressed in the monitoring network. **Please modify the description of the monitoring network to provide methodologies, data and other information to address the data gaps associated with GDEs and ISWs. This modification should include 1) locating new wells that are appropriately screened to detect changes in groundwater levels in the uppermost water table and the connectivity of GDEs and ISWs with the upper unconfined or shallow zone aquifer; and 2) identifying or installing additional stream gauges in areas where there is potential for ISWs and GDEs. Please expand on the discussion of how the new well and stream data will be used to improve ISW mapping and inform an adequate analysis, and how the data will be used to verify possible GDEs.**
- *[Minor changes to GSP text were made but did not adequately address the comment.]* As stated above in the comments for Checklist Items 8-10, **please address data gaps along the Kern River and tributary creeks identified earlier in the GSP in this section of the GSP to improve ISW mapping in companion or future GSPs (e.g., through shallow monitoring wells, stream gauges, and nested/clustered wells)**.

Checklist Items 50 and 51 – Projects and Management Actions (23 CCR §354.44)

[Section 4 Projects and Management Actions (p. 217)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* Table 4-1 in this chapter lists many important projects and management actions including allocation changes, imports, surface water diversions, pumping allowances, conveyance and recharge projects, and addition of percolation basins; however, the descriptions only identify benefits to water level, groundwater storage, water quality and water supply. Maintenance or recovery of groundwater levels and construction of recharge facilities may have potential environmental benefits. It would be advantageous to recognize these benefits so as to demonstrate multiple benefits from a funding and prioritization perspective.
    - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue**.
    - If ISWs and GDEs will not be adequately protected by the listed projects and management actions, **please consider additional management actions and projects targeted for protecting ISWs and GDEs.**
    - **Please describe how the projects and management actions will be evaluated to assess whether adverse impacts to GDEs may occur and/or will be mitigated or prevented.**
    - For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

Attachment C

Freshwater Species Located in the Kern County Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Kern County Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[2]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[3] as well as on TNC's science website[4].

Scientific Name	Common Name	Legally Protected Species		
		Federal	State	Other
BIRDS				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	Bird of Conservation Concern	Special Concern	BSSC - First priority
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anas strepera	Gadwall			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron			
Aythya affinis	Lesser Scaup			
Aythya americana	Redhead		Special Concern	BSSC - Third priority
Aythya collaris	Ring-necked Duck

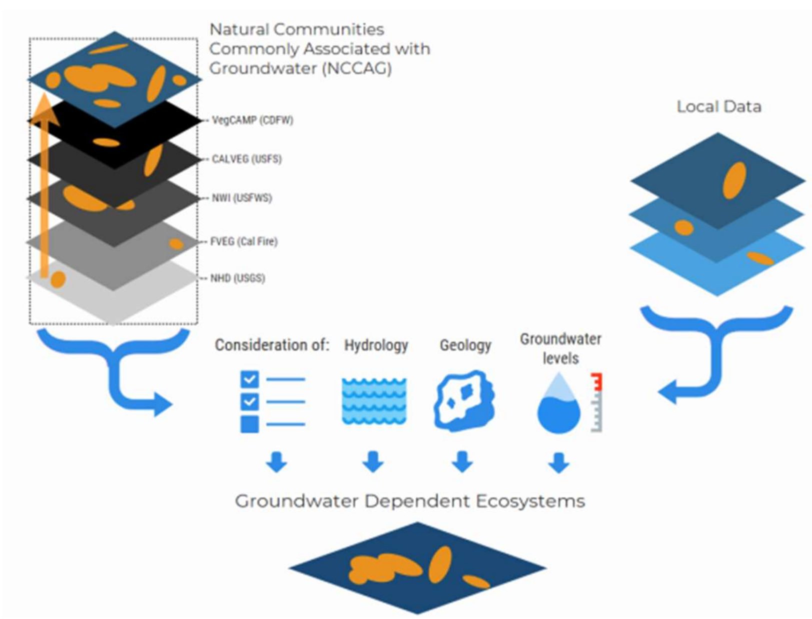
IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[5] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[6]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[5] *NC Dataset Online Viewer:* https://gis.water.ca.gov/app/NCDatasetViewer/

[6] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[7]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[8] on the Groundwater Resource Hub[9], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

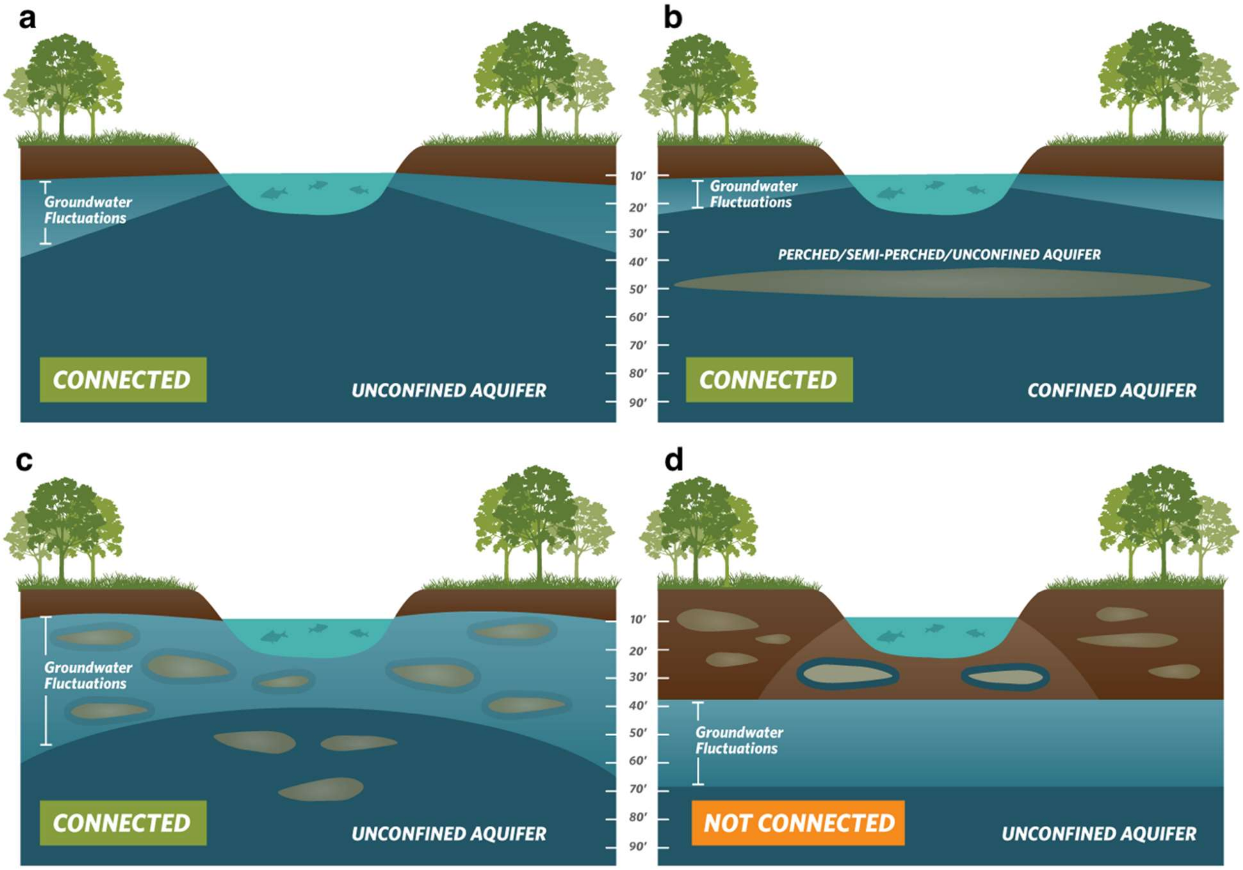

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[10] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[11] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[12] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[13]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

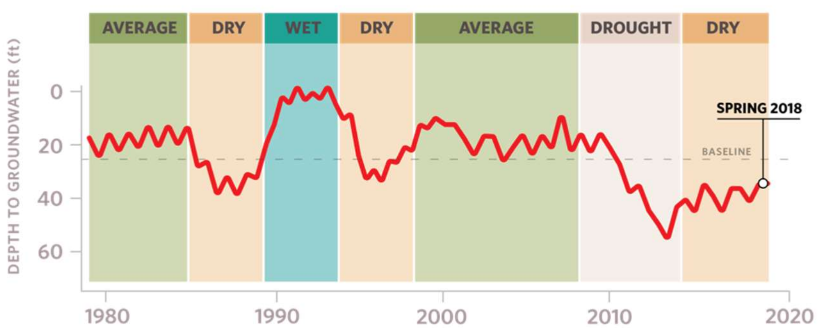

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[11] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[12] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[13] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[14], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

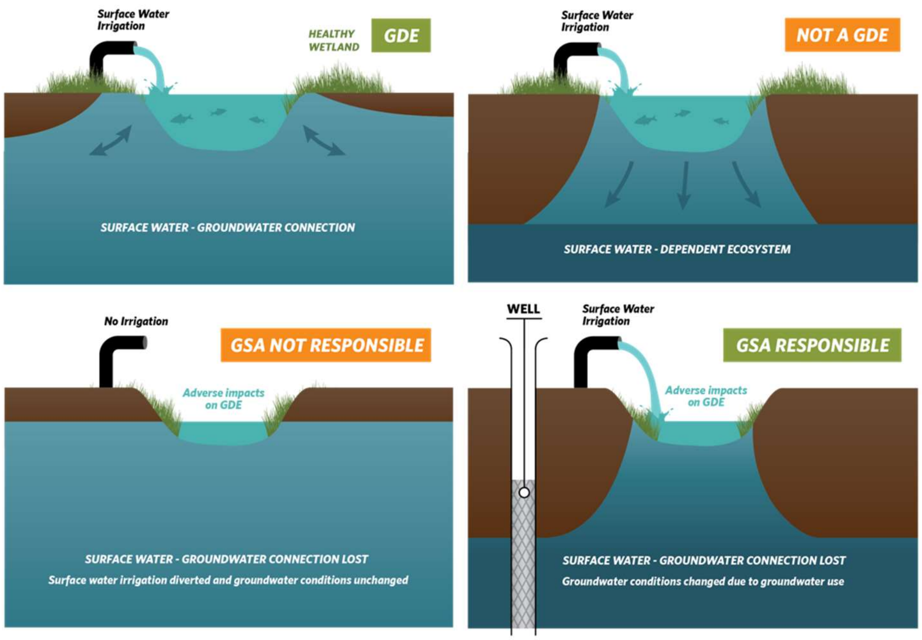

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

---

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

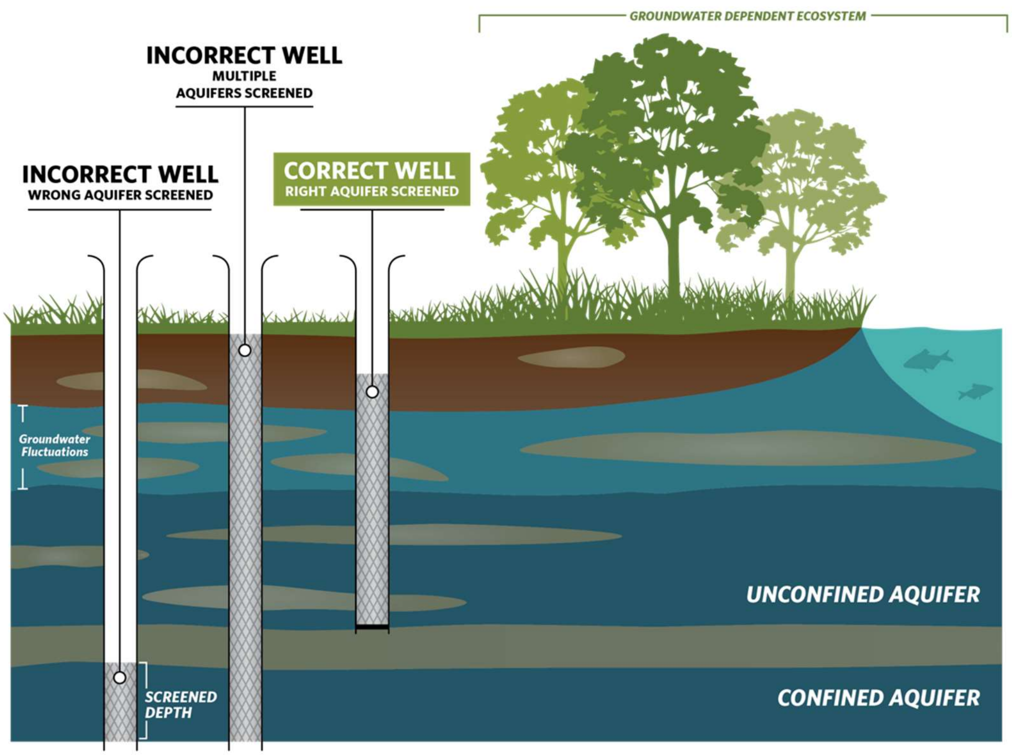

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[15] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

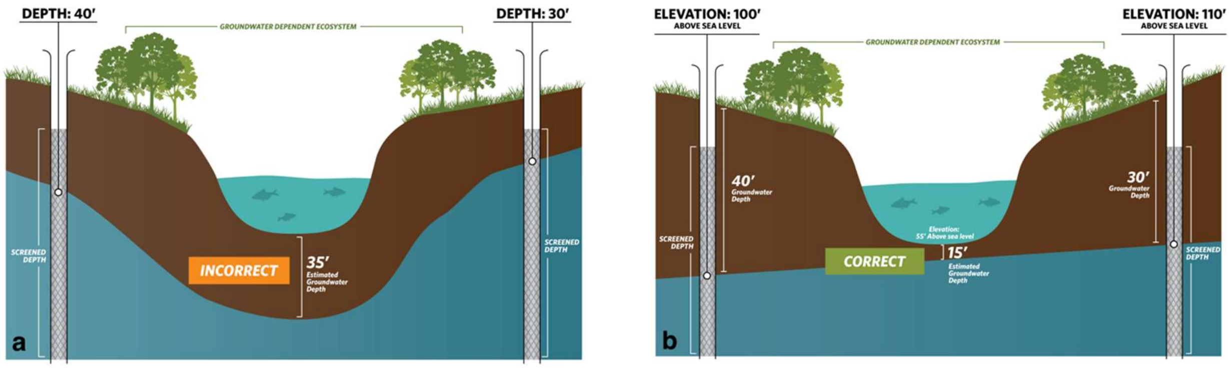

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

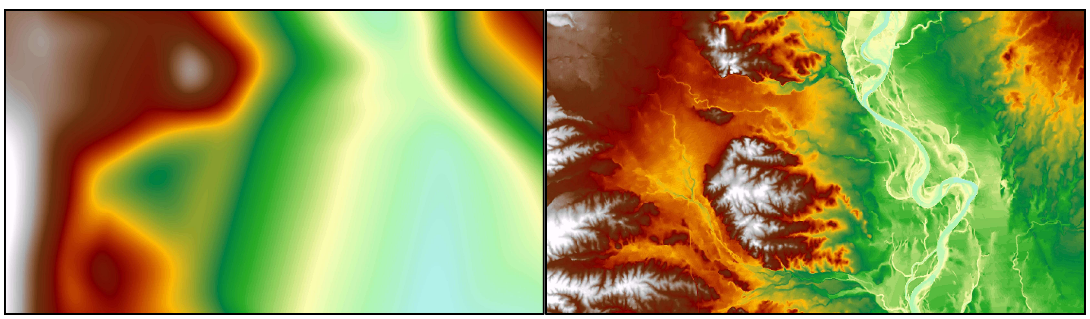

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[15] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

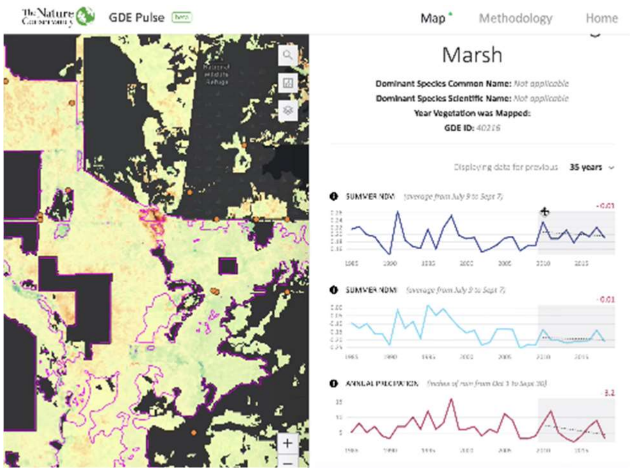
The Nature Conservancy
Protecting nature. Preserving life.®

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[16]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[17]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Attachment G

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

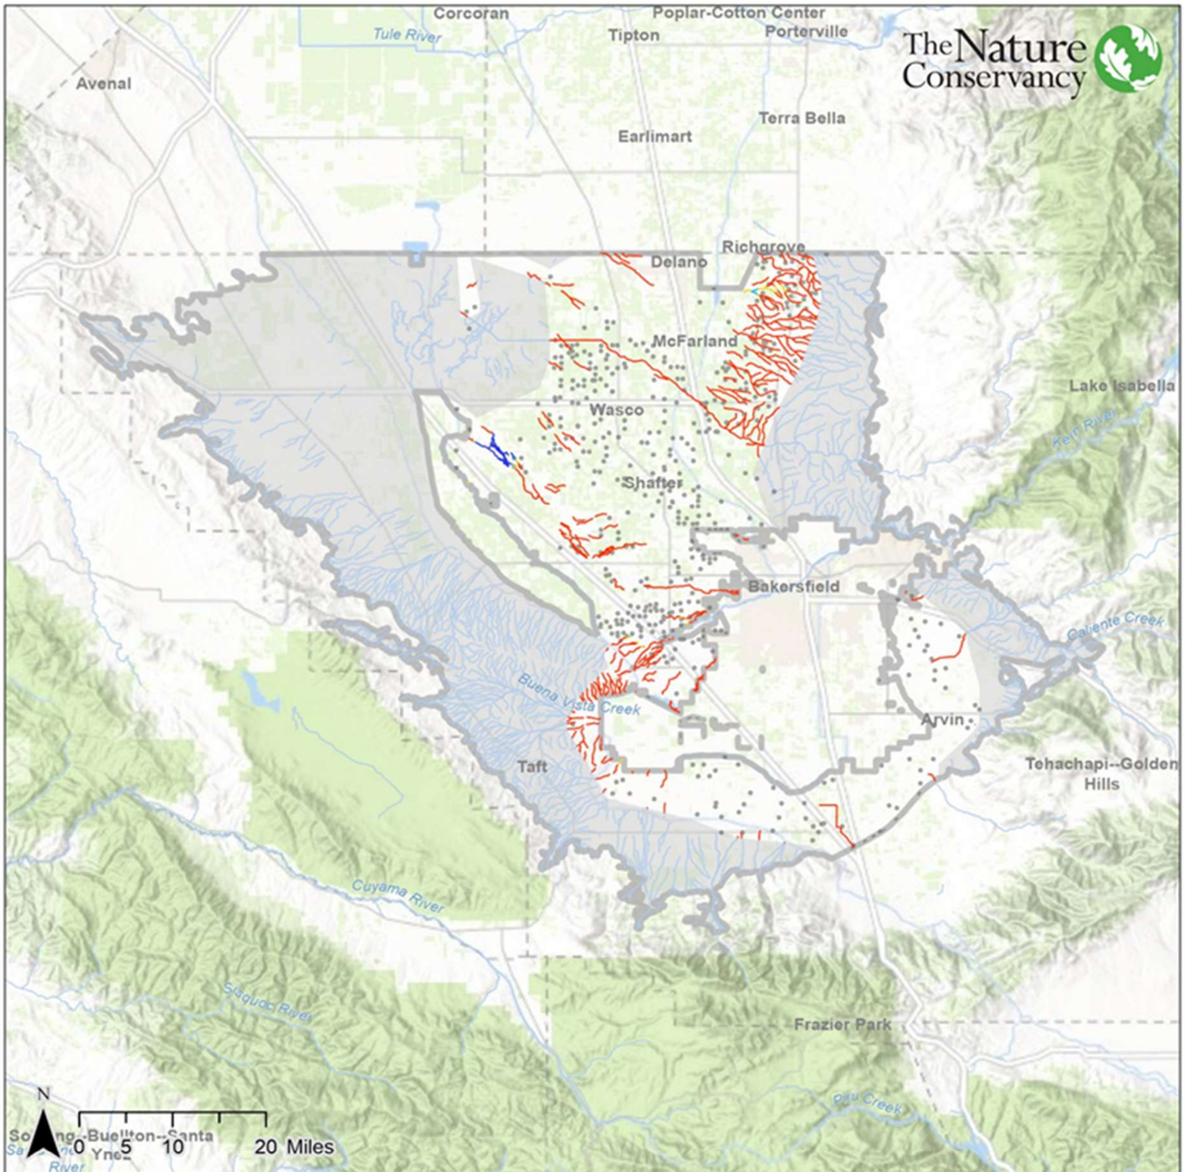
The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2011-2018)

Kern Groundwater Authority GSP



Legend

- Groundwater Sustainability Agency (GSA)
- No groundwater depth data available
- Rivers and streams with no depth data (1819 miles)
- Groundwater Elevation Monitoring Point

Minimum Groundwater Depth

- Connected - Gaining: Groundwater at or above stream surface (16.3 miles)
- Connected - Losing: Groundwater within 20 feet of stream surface (1.7 miles)
- Uncertain*: Groundwater within 20-50 feet of stream surface (7.5 miles)
- Likely Disconnected*: Groundwater greater than 50 feet below stream surface (369.3 miles)

**Streams could be connected to riparian or perched aquifers or shallow aquifers that are poorly characterized. More data are needed to confirm disconnected status.*

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[18]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[19]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[20] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Kings River East Groundwater Sustainability Plan (GSP), Kings Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Kings River East Groundwater Sustainability Agency's (GSA's) Kings River East Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of ISWs.

<u>Our Key Considerations</u>

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP have been largely ignored in the final plan, as only 6 out of 64 of our comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

<u>TNC recommendation</u>: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were not consistently or adequately analyzed in the GSP. The GSP does recognize one reach of the Kings River than is in hydraulic connection to groundwater. However, the GSP does not explain how this interconnected reach was identified or estimate the quantity and timing of streamflow depletions. Our analysis of groundwater levels from 2011 to 2018 indicate ISWs are more extensive than estimated in the GSP, including all of the branches of the Kings river, portions of the Kings river downstream of Reedley, and Wahtoke Creek (see Attachment G). In addition, the plan does not consider the other streams in the subbasin. Furthermore, despite only two wells in the proposed monitoring network for ISWs, the GSP states that there are no data gaps in monitoring for ISWs. Therefore, potential ISWs may not be managed in the GSP.

<u>Map and Assessment of potential ISWs</u>:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the Kings River East GSP, 17.8 river miles are gaining, 51.5 are losing, and the rest are uncertain or likely disconnected (based on streams with available groundwater depth data). Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the

minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

<u>TNC recommendation</u>: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on surface water-groundwater interconnectivity and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 4,047 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not to adequately identify, map and consider GDEs. We believe that this does not meet plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on groundwater levels that were greater than 30-feet at a <u>single point in time</u>. This is a technically incorrect approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30-ft or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unprotected in the GSP.

<u>TNC recommendation</u>: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in Attachment D on best practices for utilizing the NC dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). The GSP only focused on a subset of water use sectors, including urban and agricultural users of groundwater. This is problematic because key environmental uses of groundwater are not being accounted for as water supply

[1] *Available at:* https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

decisions are made using this budget nor will they likely be considered in project and management actions.

TNC recommendation: As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Potential GDEs are located along surface water bodies where no shallow groundwater monitoring currently exists or is proposed, leaving data gaps unfilled. Potential ISWs have been dismissed in the GSP, without proposed recommendations to improve ISW identification, mapping, and estimates of depletions. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Kings River East Groundwater Sustainability Plan
Comments based on Draft and Final GSPs

The Kings River East Area Groundwater Sustainability Plan (GSP) adopted December 13, 2019 was reviewed by TNC. Public draft GSP comments and responses, provided as Appendix 8A of the GSP, were reviewed and are referred to below. The TNC comments and responses are also provided in Attachment F of this letter. This attachment lists our original comments on the complete public draft GSP as submitted to the GSA during the public comment period, and states whether or not they were addressed in the final GSP [as green text within brackets]. Comments are provided in the order of the checklist items included as Attachment A.

Overall Comment on the GSP

- *[The GSP is improved in this regard but there are still figures missing and incorrect callouts. See individual comments below for specific issues.]* Key sections of the document were not provided in the public draft, such as the map of GDE areas and Sustainable Management Criteria for Interconnected Surface Waters. **Please carefully check the document for completeness, missing figures, missing figure references, mis-labeled figures, and formatting. Where pertinent to our review, specific issues are called out below.**

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 2.5.1 Description of Beneficial Uses and Users (p. 2-34)]

- *[The GSA's response of "Thank you for your comments. All comments are given due consideration" does not address our comment and no changes to the GSP text were made.]* The discussion of beneficial uses and users of groundwater focuses on agricultural users, public and private water supply systems, and disadvantaged communities. The GSP states (p. 2-34): "KREGSA is not aware of any environmental users of groundwater within KREGSA." There are riparian areas along the Kings River where wildlife is supported by the river and shallow groundwater. In addition, possible GDEs have been identified in the KREGSA. **Please discuss if any environmental groups were engaged during the GSP development process. Acknowledge that there are environmental users of groundwater including GDEs and those supported by ISWs.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please identify whether or not the following beneficial uses and users of groundwater in the Subbasin are present: Protected Lands, including refuges, conservation areas, and recreational areas; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The types and locations of environmental uses, species and habitats supported, instream flow requirements, and other designated beneficial

environmental uses of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. **To identify environmental users, please refer to the following:**

- The NC Dataset (https://gis.water.ca.gov/app/NCDatasetViewer/) which identifies the potential presence of groundwater dependent ecosystems in this basin.
- The list of freshwater species located in the Kings Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.
- CDFW's California Natural Diversity Database (CNDDB) - https://www.wildlife.ca.gov/Data/CNDDB
- USFWS's IPAC report for the KREGSA - https://ecos.fws.gov/ipac/

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8).

[Section 2.2.1 Groundwater Level Monitoring (p. 2-18)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The Kings River Conservation District (KRCD) oversees groundwater level data collection in the KREGSA. **Please describe how existing groundwater monitoring programs are protective of GDEs or propose additional monitoring that specifically targets GDEs.**

[Section 2.2.9 Surface Water Monitoring (p. 2-22)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section states that the Kings River is monitored by the Kings River Water Association, with emphasis on snowpack and reservoir inflows and outflows. There is no mention that the Kings River flow requirements include maintenance of a 10 percent minimum capacity in the Pine Flats Reservoir for improved temperature control and year-round fish releases below the reservoir. There is no mention of ISWs or GDEs or how they are monitored. **Please explain the relationship of existing stream flow monitoring to the protection of ISWs and GDEs.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The GSP discusses the uncertainty of Kings River flood flows in the future. The SWRCB has declared the Kings River to be a "fully appropriated stream" (p. 2-23). This status has been challenged by the Semitropic Water Storage District of Kern County. Flood flows of the Kings River could be transferred out of the subbasin into Kern County. **Please discuss how this transfer, if it occurs, could impact the GDEs and ISWs in the KREGSA.**

[Section 2.3.1 Summary of General Plans (p. 2-25)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The Fresno and Tulare County General Plan and the City General Plans of Dinuba, Orange Cove, and Reedley were adopted prior to the development of the GSP. This section should be modified to include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin, and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**

[Section 2.3.4 Permitting New or Replacement Wells (p. 2-26 to 2-28)]

- *[Our comment was adequately addressed through GSP text changes. Thank you for acknowledging the environmental importance of proper well permitting and coordination with the GSP to ensure sustainable groundwater management.]* Well permitting is currently managed by the Fresno and Tulare County Health Departments. Both counties require new, repaired or replacement wells to have a permit and require adherence to DWR standards. **Please include a discussion of how future well permitting will be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF vs. SWRCB and Siskiyou County, No. C083239). **Compliance of well permitting programs with this requirement should be stated in the GSP.**

<u>Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)</u>

[Section 3 Basin Setting (p. 3-1 to 3-125)]

- *[The GSP improved the figures in this section but there are still problems with the callouts. For example, on page 3-79 the callout for Figure 3-31 should be to Figure 3-35. Please re-check all figures and callouts in this section.]* There are several problems with figures in Section 3. The numbering is off by one, beginning on page 3-31, when the text refers to Figures 3-15 to 3-20, but the numbers should be Figures 3-16 to Fig 3-21. The figure after page 3-43 has no number. It is referred to both as Figure 3-21 and 3-22. Figure 3-22 numbering is probably correct, but it does not show all the rivers and creeks listed in the text. The land subsidence section refers to Figure 3-25, which has the KRCD subsidence monitoring locations

[2] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

on it, but is included later as Figure 3-29 after page 3-70. Figure 3-26 is not mentioned at all. Figure 3-27 (NASA 2015-1017 lnSar data provided by DWR) is missing. Figure 3-28 (GDE map with included and excluded units) referenced on page 3-70 is missing. **Please provide missing figures and check numbering of all figures in Section 3.**

[Section 3.1.3 Regional Geologic and Structural Setting (p. 3-4 to 3-7)]

- *[The GSA's response does not address our comment. Changes were made to the GSP text but our comment was not addressed.]* In the eastern part of the KRE GSA, the base of the aquifer is defined by the bedrock. In the western part, the bedrock is deeper as shown in Figure 3-3. The base of the usable aquifer corresponds with the base of freshwater, generally defined as groundwater with total dissolved solids (TDS) of 2,000 milligrams per liter (mg/l), consistent with other GSAs in the Kings subbasin. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.

[Section 3.1.7 Cross-Sections (p. 3-20 to 3-35)]

- *[The GSP figure numbers in this section were updated. Other requested figure changes were not made.]* The cross-sections across the Kings River East depict the general types of formation (e.g., sand or clay) and the water surface based on the Fall 2013 level, but do not show the base of freshwater. In cross-section C-C', there were two composite wells, AR No, 4 and Kingsburg No. 12, with multiple screened intervals, so the water level does not represent the shallowest groundwater. Cross-sections B-B' and C-C' are mis-labeled; B-B' should be Figure 3-14 and C-C' should be Figure 3-15. **Please correct the figure number labels and add the base of freshwater where pertinent to these cross-sections.**
- *[The GSA's response does not address our comment and no changes to the GSP figures were made.]* The basin-wide cross sections provided in Figures 3-15 through 3-20 are regional, and do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. The cross-sections have been taken from a 1969 source and, as reproduced in the GSP, are very difficult to read and understand. **Please reproduce the regional cross-sections so that they can be understood by the reader and update them to illustrate data obtained from more recent well installations. Include an example near-surface cross sections that depicts the conceptual understanding of shallow groundwater and river interactions at different locations, as well as any potential GDEs and ISWs**.

[Section 3.1.8.4 Confining Beds (p. 3-44)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The Corcoran Clay is present in the southwestern part of the subbasin. There are local confining beds at depths of 200 to 300 feet in the basin. Some recent irrigation wells have been screened in the deep confined groundwater. This section appears to contradict the sentence on page 3-105 which states "There are no known confined aquifers in KREGSA," and in Section 5 Monitoring Network, where the GSP states that there is "a confined aquifer covering a smaller portion of the southwestern edge of KREGSA" (p. 5-7). **Please revise the text in Section 3 and provide additional discussion and reference a map to explain where the wells screened in confined groundwater are located.**

[Section 3.1.10 Surface Water Features (p. 3-45)]

- *[The GSP figure was revised to incorporate our comments. Thank you for showing these important surface water features on this map.]* This section discusses the major river in the KREGSA, the Kings River, and shows the river and the major diversions on Figure 3-23. The other creeks are mentioned in the text, but are not shown in the figure. The canal system of the Alta Irrigation District is also mentioned, as is the Cobbles Weir. The weirs shown on the map include one for a diversion out of subbasin, shown in red, which is not used. **Please revise the figure to show all the creeks, the canals of Alta ID including the Cobbles Weir, Fresno Weir, and Peoples Weir, other weirs from Kings River and the Friant-Kern Canal.**

[Section 3.1.12 Recharge and Discharge Areas (p. 3-48 to 3-53]

- *[A description and figure of wetland areas was added to the GSP text. Please further describe these areas and state whether features are present that attract wildlife and if habitat could be included in an HCP or NCCP.]* The GSP states that there are intentional recharge basins. No specific names of recharge basins are given here or noted in the water budget section. **Please include the names and description of these areas and if they note whether any features are present that attract wildlife. Please indicate whether the recharge basins are or could be operated as multiple-benefit projects that provide habitat suitable for migrating birds or other species, and could be included in an HCP or NCCP.**
- *[The revised GSP text refers to Figure 3-28 in this section for groundwater discharge areas but they are not evident on the figure. Our comment was not addressed.]* **Please include missing Figure 3-24, which shows the locations of groundwater discharge areas.**

<u>Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)</u>

[Section 3.2.10 Interconnected Surface Water Systems (p. 3-79)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The Interconnected Surface Water Systems section appears to be incomplete. The text states that shallow groundwater is in hydraulic communication with stream flow in the Kings River upstream of the city of Reedley, but gives no further details. Other Kings Basins GSPs (for example, Central Kings and North Kings) discuss the draft HCM and Groundwater Conditions report for the Kings River area prepared by KDSA 2017. **Please further describe the ISWs in the KREGSA citing this report and other available information. Per the regulations cited on page 3-69 of the GSP, estimate the quantity and timing of depletion of those systems, utilizing best available information.**

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please note the following best practices for analysis of ISWs.** ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface Digital Elevation Model (DEM) that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. **Please provide or refer to depth to groundwater contour maps in this section. See Attachment D for best practices for completing this step. Specifically, ensure that the first step is contouring groundwater elevations, and the subtracting this layer from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape**. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found. Contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The finding that groundwater is in direct hydraulic communication with streamflow in the Kings River cited by KDSA 2017 in other Kings Basin GSPs should be illustrated using cross-sections with measured channel bed elevations and depths to groundwater. **Please provide a cross-section to show the relationship between the depth to groundwater and the bed of the river channel. If channel bed elevations are not known, please identify as a data gap and further discuss in the Monitoring section of the GSP.**

<u>Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)</u>

[Section 3.2.11 Groundwater Dependent Ecosystems (p. 3-79)]

- *[Figures 3-34 and 3-35 were provided in the Final GSP showing GDEs in the KREGSA. Thank you for providing these figures in the Final GSP. Our comment was addressed.]* The GSP has a brief discussion of GDEs that follows the discussion of GDEs from other GSAs in the Kings Subbasin. However, the referenced Figure 3-28 is missing. The comments that follow instead refer to Figure 3-58 from the Central Kings GSP, since this figure also shows GDEs in the KREGSA. **The comments on this section should therefore be considered preliminary until a final Figure for GDEs in the KREGSA is provided.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The NC dataset is a starting point for GSAs to identify GDEs in their basin/subbasin. The NC dataset has 4,047 acres of potential GDEs mapped within the

KREGSA, representing a significant amount of GDEs to be considered. Note that this is a starting point, thus not all potential GDEs are mapped and not all ecosystems mapped are GDEs. **Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled by the monitoring network.** Specifically, please note:

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The text refers to Spring of 2017 depth to groundwater contours. **Please provide more information on how these contours were developed, and note the following best practices for developing depth to groundwater contours**:
  - Only wells monitoring the upper unconfined aquifer are being used to verify whether polygons in the NC dataset are supported by groundwater;
  - The wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons reflect local conditions relevant to ecosystems;
  - The wells used for interpolating depth to groundwater are screened within the surficial unconfined aquifer and capable of measuring the true water table; and
  - Depth to groundwater is contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from measurements at wells assume that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to create the contour map.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Spring 2017 is after the SGMA benchmark date of January 1, 2015. **Ensure that groundwater condition data prior to the SGMA benchmark date of January 1, 2015 is included in the analysis.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* It is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2017) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine**

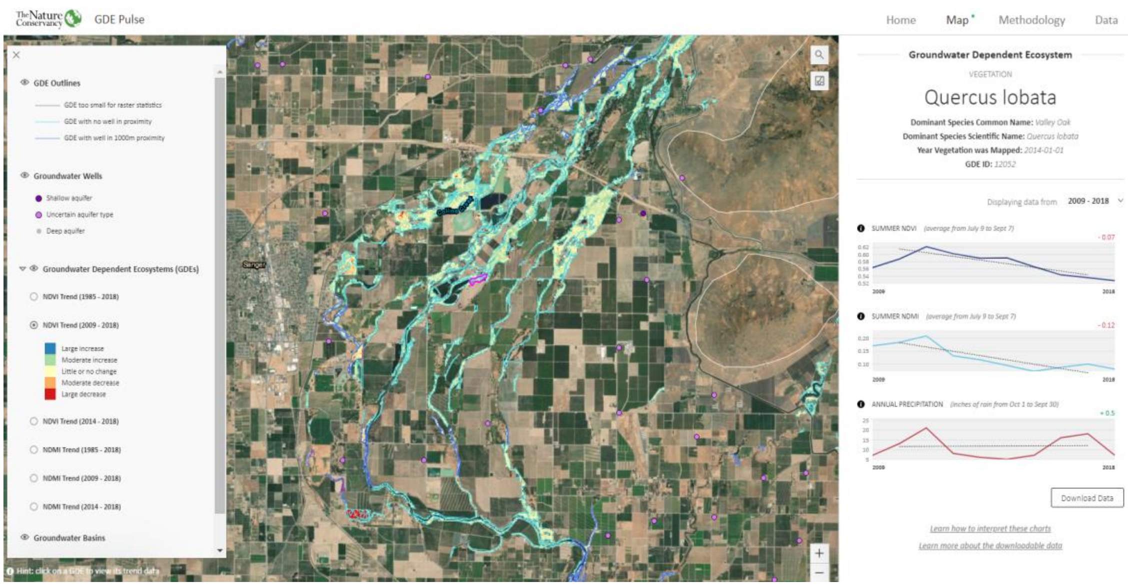
the range of depth to groundwater around NC dataset polygons. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network.

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please provide rationale for the 30-foot criteria cited in the text.** The text states (p. 3-69): "Recognizing that much of the Kings Subbasin has a depth to groundwater greater than the deepest vegetative GDE rooting depth of thirty feet, many of the GDEs identified in the NC Dataset Viewer were mischaracterized." In TNC's GDE Guidance, the depth criteria of 30 feet is presented as a criterion for *inclusion*, not a standalone criterion for *exclusion*. In other words, if groundwater is within 30 feet of the ground surface, then a GDE can be identified. If it is not, then further analysis must be conducted (see Appendix III of the GDE Guidance, Worksheet 1, for other indicators of GDEs). **Please indicate what vegetation is present in the possible GDEs.** The actual rooting depth of vegetation growing in the area should be considered, and this will vary by species dominance and habitats present. For example, some phreatophytes can root to 120-feet deep in more arid and drought stressed environments. Furthermore, rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant. Maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not prefer to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths.
- *[One sentence added to GSP text: "This 100-ft buffer is based on a California Department of Transportation typical wetland setback (CDOT, 2019)." However, this addition to the text does not address our comment nor does this buffer rule describe whether groundwater conditions in the basin are supporting GDEs.]* The text states: "The Kings Subbasin also categorized GDEs within 100 feet of the Kings River and the San Joaquin River as "Possible GDEs." **Please clarify how the 100-foot buffer was used to include or exclude GDEs in the KREGSA area, and how this is supported by groundwater level and plant physiological data. If there is a potential GDE near the river, we suggest the entire GDE is included, rather than using an arbitrary 100-foot cutoff.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **In the text, please cite the acreage of GDEs retained and removed. The basin's GDE shapefile, which is submitted via the SGMA Portal, should include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).**

Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)

[Section 3.2.11 Groundwater Dependent Ecosystems (p. 3-79)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present**. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the KREGSA:



- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please provide an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes the vegetation types or habitat types and rank the GDEs as having a high, moderate or low value; and what characterizes the rank.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat, were found in or near any of the GDEs, since some organisms rely on uplands and wetlands during different stages of their lifecycle**. Resources for this include the list of freshwater species located in the Kings Subbasin that can be found in Attachment C of this letter, the Critical Species Lookbook, and CDFW's CNDDB database.

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **For each identifiable GDE unit with supporting hydrological datasets please include the following:**
    - Plot and provide hydrological datasets for each GDE.
    - Define the baseline period in the hydrologic data.
    - Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater.
    - Explore cause-and-effect relationships between groundwater changes and GDEs.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **For each identifiable GDE unit without supporting hydrological datasets please describe data gaps and/or insufficiencies.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Compile and synthesize biological data for each GDE unit by including:**
    - Plots of biological datasets for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.
    - Describe data gaps/insufficiencies.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Describe potential effects on GDEs, land uses, and property interests, including:**
    - Cause-and-effect relationships between GDE and groundwater conditions.
    - Impacts to GDEs that are considered to be "significant and unreasonable".
    - Report known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities.
    - Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).
    - Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 3.3.8 Historical Water Budget (p. 3-106)]
[Section 3.3.9 Current Water Budget (p. 3-110)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please clarify whether a term is included for native or riparian vegetation evapotranspiration in the KREGSA historical, current, and projected water budgets.**

[Section 3.3.10 Projected Water Budget (p. 3-114)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Given the uncertainty associated with Kings River water supply into the future, the assumption was made that the historical water delivery from the Kings

River would be maintained. This assumption is highly uncertain and is not conservative. The diversion of Kings River flows may require additional provision for storage in the non-irrigation or low-irrigation season. **Please add discussion of the potential impacts to the flow in the Kings River and to groundwater conditions on GDEs, aquatic ecosystems and instream flow requirements due to climate change.**

Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)

[Section 4.1 Sustainability Goal (p. 4-2)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Since GDEs are present in the KREGSA, they should be recognized as beneficial users of groundwater and should be included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* GDEs are dependent, in part, on suitable water quality; however, the GSP only considers water quality for irrigation and domestic use. **TNC recommends including ISWs and their potential GDEs in the sustainability goal and criteria. Since GDEs may be affected by water quality, they should be included in the Sustainability Goal.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Sections 4.2.3 Measurable Objectives for Groundwater Levels (p. 4-20)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This Measurable Objective does not consider GDEs. GDEs are often adjacent to streams or associated with riparian corridors where ISWs exist, even if only seasonally or discontinuously along a longitudinal or lateral profile. **Please include GDEs (see comments under Checklist Items 8-10) in this section and state whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.3 Measurable Objectives for Water Quality (p. 4-41)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This Measurable Objective does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Section 4.7.3 Measurable Objectives for Interconnected Surface Water (p. 4-70)]

- *[This previously missing section was added to the document.   However, Sustainable Management Criteria were not set for ISWs, so our original bolded comment still applies.]* The Sustainable Management Criteria section for Interconnected Surface Water is missing from the document. **Because ISWs exist in the KREGSA,**

Sustainable Management Criteria must be developed for this sustainability indicator.

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The text states (p. 4-9): "Water levels will not be used as proxy for the other sustainability indicators." However, the text also states (p. 5-43): "Water level will be used as a proxy for the interconnected surface water sustainability indicator." Furthermore, in the Monitoring section, the GSP states (p. 5-39): "The groundwater level minimum threshold elevations in the indicator wells (Section 4.2) in the area of the Kings River below the Fresno Weir were used to determine the sustainable management criteria for interconnected surface water," implying that groundwater elevations are used as a proxy for the depletion of surface water suitability indicator. **Please clear up these apparent inconsistencies in the text.**

Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28)

[Sections 4.2.2 Minimum Thresholds for Groundwater Levels (p. 4-8)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This Minimum Threshold does not consider GDEs or ISWs. **Please include GDEs and ISWs in this section and discuss whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.2 Minimum Thresholds for Groundwater Quality (p. 4-36)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This Minimum Threshold does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Section 4.7.2 Minimum Thresholds for Interconnected Surface Water]

- *[This previously missing section was added to the document. However, Sustainable Management Criteria were not set for ISWs, so our original bolded comment still applies.]* As stated above, the Sustainable Management Criteria section for Interconnected Surface Water is missing from the document. **Because ISWs exist in the KREGSA, Sustainable Management Criteria must be developed for this sustainability indicator.**

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 4.2.1 Undesirable Results for Groundwater Levels (p. 4-4)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses and users that could be adversely affected by chronic groundwater level decline. **Please add**

potential adverse impacts to GDEs and native freshwater species to the discussion of potential undesirable results presented in this section.

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The GDE Pulse web application developed by TNC provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within and near the GSA. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture along the Kings River. An example screen shot from the GDE Pulse tool is presented under Checklist Items 11-15 above.

[Section 4.5.1 Undesirable Results for Groundwater Quality (p. 4-32)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section describes undesirable results in terms of meeting drinking water standards and irrigation water quality. **Any potential undesirable results from degradation of water quality that may impact GDEs and freshwater species in the area should be discussed in this section.**

[Section 4.7.1 Undesirable Results for Interconnected Surface Water]

- *[This previously missing section was added to the document. However, Sustainable Management Criteria were not set for ISWs, so our original bolded comment still applies.]* As stated above, the Sustainable Management Criteria section for Interconnected Surface Water is missing from the document. **Because ISWs exist in the KREGSA, Sustainable Management Criteria must be developed for this sustainability indicator.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The analysis of ISWs should include all beneficial uses and users of surface water that could be affected by groundwater withdrawals, including environmental users. **Please state in this section whether there are any instream flow requirements and critical habitat designations and set measurable objectives and interim milestones to help achieve the sustainability goal as it pertains to the environment.**

<u>Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)</u>

[Section 5.2 Groundwater Level Monitoring (p. 5-6 to 5-16)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please address how the requirement to link and correlate groundwater level declines to biological responses and significant and adverse impacts to GDEs and ISWs will be addressed by the monitoring network.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The proposed 22 wells to be used for monitoring groundwater levels are shown on Figure 5-2 (p. 5-5). However, there is no indication on the figure which wells have well construction information. Some of the wells used in the cross-

sections had multiple screened intervals and some had deep screened intervals, which make them unsuitable as unconfined groundwater monitoring sites. The text states that where well information is not obtained, other wells may be selected by 2025. **Please elaborate on plans to collect well construction information as soon as possible. To accurately characterize GDEs, please clarify how the unconfined aquifer will be monitored and how many wells will be used.**

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* In Section 5.2.8.2 Identification of Data Gaps (p. 5-14), the text refers to the NKGSA instead of the KREGSA and mentions a spatial data gap along the eastern part of Highway 68. There are apparent spatial data gaps in the southwest part of the KREGSA west and south of Traver and to the northeast of Reedley. **Please provide discussion of the spatial data gaps in the monitoring network for the KREGSA and how they will be filled.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Possible GDEs were identified along the foothills and within 100 feet of the Kings River. **To accurately characterize GDEs, please describe how the unconfined aquifer will be monitored and how many wells will be used. Please clarify how many of the wells on Figure 5-2 represent the unconfined aquifer.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The text mentions that the GSA seeks to refine the understanding of a confined aquifer due to multiple clay layers in the eastern area where the Corcoran Clay is absent. The monitoring program may be expanded in the future, if there are sufficient wells tapping the confined aquifer, such that two monitoring programs for the unconfined aquifer and the confined aquifer would be established. **Please identify any existing wells in the known confined aquifer and at what depths confined conditions are understood to exist.**

[Section 5.7 Depletion of Interconnected Surface Water Monitoring (pp. 5-39 to 5-45)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater ***and related surface conditions*** (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of complicated factors, and this relationship is not characterized or discussed. As such, it is not possible to determine whether the proposed monitoring is sufficiently protective to ensure significant and unreasonable impacts to GDEs and ISWs will be prevented. **To clarify if GDEs are present, consider adding monitoring of potential GDEs at any locations where ISWs are present regardless of their seasonal or discontinuous nature.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The wells shown in Figure 5-2 include two wells that have been identified to monitor unconfined groundwater in the vicinity of the interconnected

portion of the Kings River. These wells are KRWD04 and B013B. The location of the river channels and sloughs and the location of the Fresno Weir are not shown on this map, so it is difficult to tell how far the wells are from the river. In addition, the depth and screened interval are not provided for the two wells. Thus, it is not possible to determine if the monitoring is adequate. In the text (p. 5-41) a Figure 5-4 was referenced but not included. **Please provide the missing figure and a description of any sites where flow and channel depth will be measured. Please provide well construction information for these two wells and distances from the river. Please show the river channel depth and location in reference to these wells, along with the screened interval of the wells.**

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section is entitled "Depletion of Interconnected Surface Water Monitoring," however the GSP states (p. 5-45): "There are no identified data gaps in the groundwater *quality* (emphasis added) monitoring network at this time." Please identify data gaps in the monitoring of ISWs. **Please reconcile the limited monitoring for ISWs with specific recommendations (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features to improve ISW mapping and inform an adequate analysis.**

<u>Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)</u>

[Section 6.1 Introduction (p. 6-1)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The KREGSA includes GDEs and ISWs (see our comments under Checklist Items 8-10 and 16-20 above) that are beneficial uses and users of groundwater and may include potentially sensitive resources and protected lands. Environmental beneficial users and uses should be considered in establishing project priorities. In addition, consistent with existing grant and funding guidelines for SGMA-related work, consideration should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**

[Section 6.2 Projects (pp. 6-2 to 6-34)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section identifies multiple recharge projects; however, the descriptions of Measurable Objectives for these projects only identifies benefits to water level, groundwater storage, and degraded water quality. In most cases, the water source and the funding have not been identified, increasing the uncertainty of the project being implemented. Because maintenance or recovery of groundwater levels or construction of recharge facilities may have potential environmental benefits, it would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.

- **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
- If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting ISWs.**
- Recharge basins, reservoirs and facilities for managed stormwater recharge projects can be designed as multi-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such multiple-benefit projects and facilities have been incorporated into local Habitat Conservation Plans (HCPs) and Natural Community Conservation Plans (NCCPs), more fully recognizing the value of the habitat that they provide and the species they support. For projects that construct recharge basins, **please consider identifying if there is habitat value incorporated into the design and how the recharge basins will be managed to benefit environmental users. Grant and funding priorities for SGMA-related work may be given to multi-benefit projects that can address water quantity as well as provide environmental benefits. Therefore, please include environmental benefits and multiple benefits as criteria for assessing project priorities.**
- For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

[Section 6.3 Management Actions (p. 6-35)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The KREGSA has listed possible management actions in Table 6-16. These actions include education and communication, improved documentation of groundwater extraction facilities, and other methods for quantifying groundwater extraction. **Please consider adding Management Actions which include education and outreach for protection of GDEs and ISWs as well as specific management of these ecosystems and the species they provide for.**

Attachment C

Freshwater Species Located in the Kings Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Kings Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[4] as well as on TNC's science website[5].

Scientific Name	Common Name	Legally Protected Species		
		Federal	State	Other
Birds				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	BCC	SCC	BSSC - First priority
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anas strepera	Gadwall			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron			
Aythya affinis	Lesser Scaup			
Aythya americana	Redhead		SCC	BSSC - Third priority
Aythya collaris	Ring-necked Duck			
Aythya marila	Greater Scaup			
Aythya valisineria	Canvasback		SCC

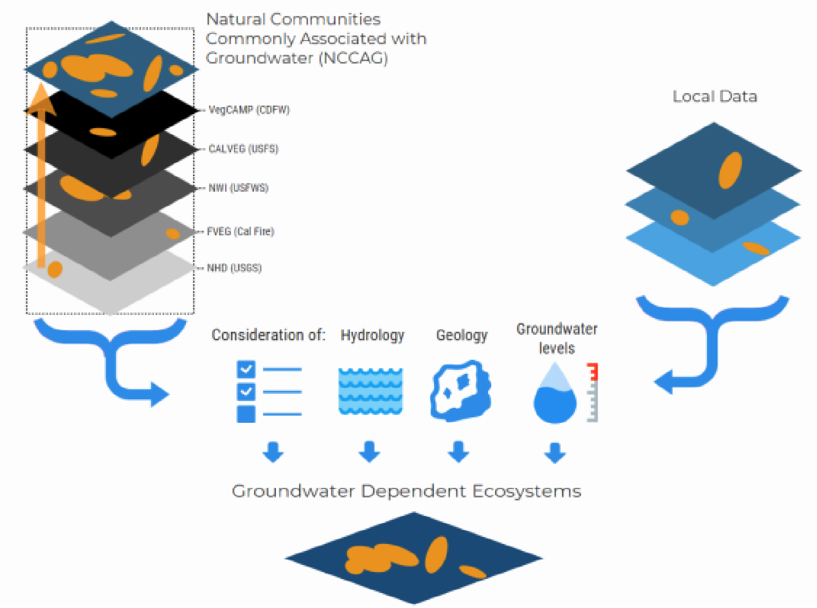
IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[6] *NC Dataset Online Viewer:* https://gis.water.ca.gov/app/NCDatasetViewer/

[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

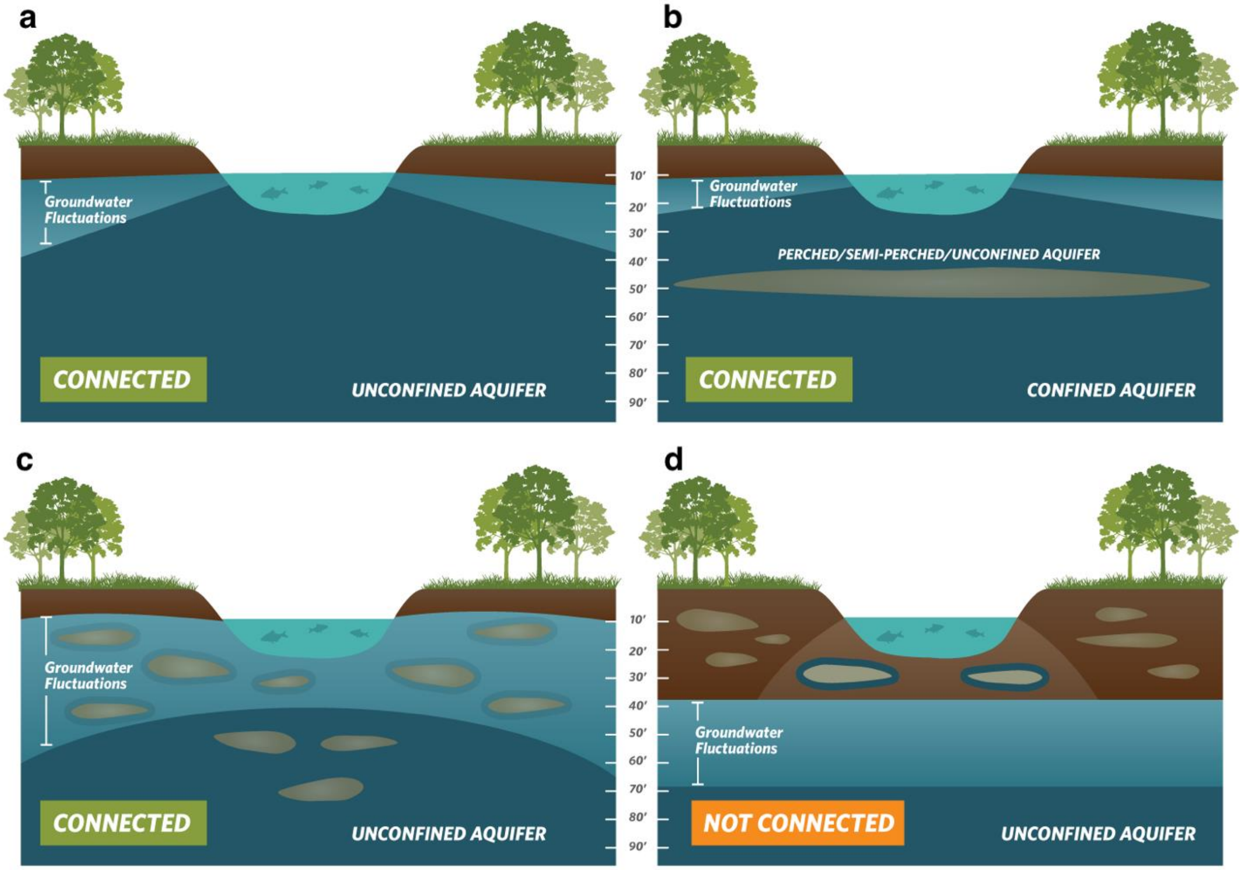

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

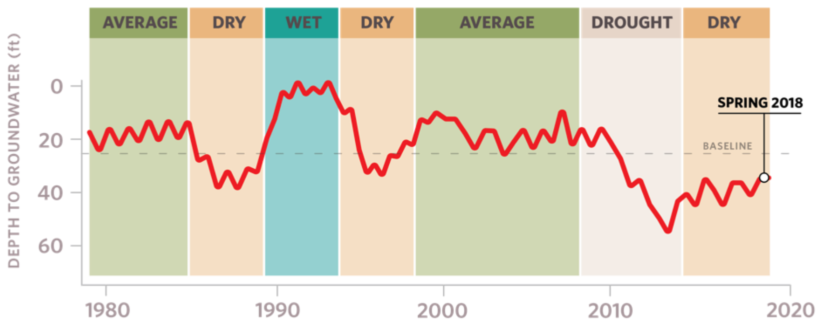

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[11] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

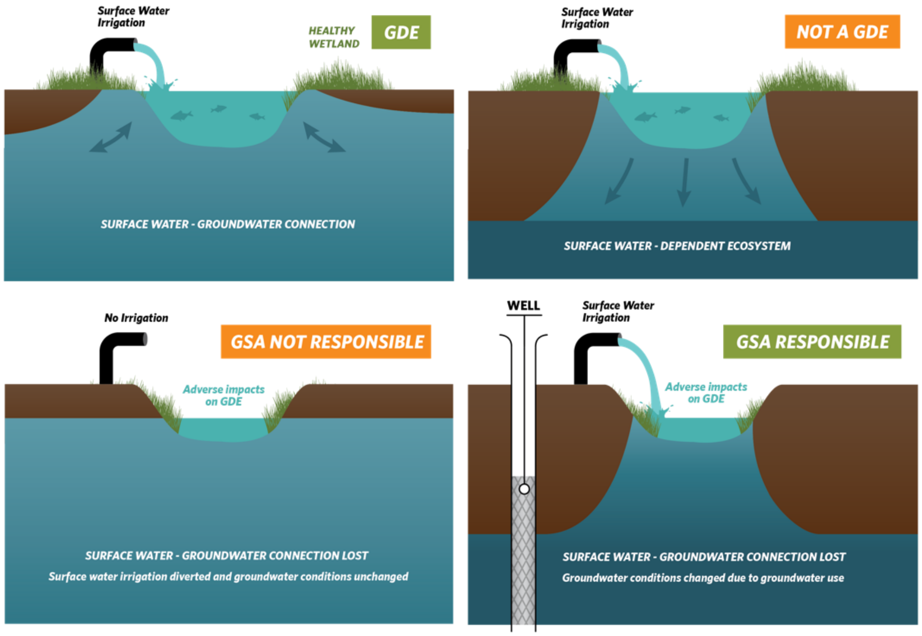

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

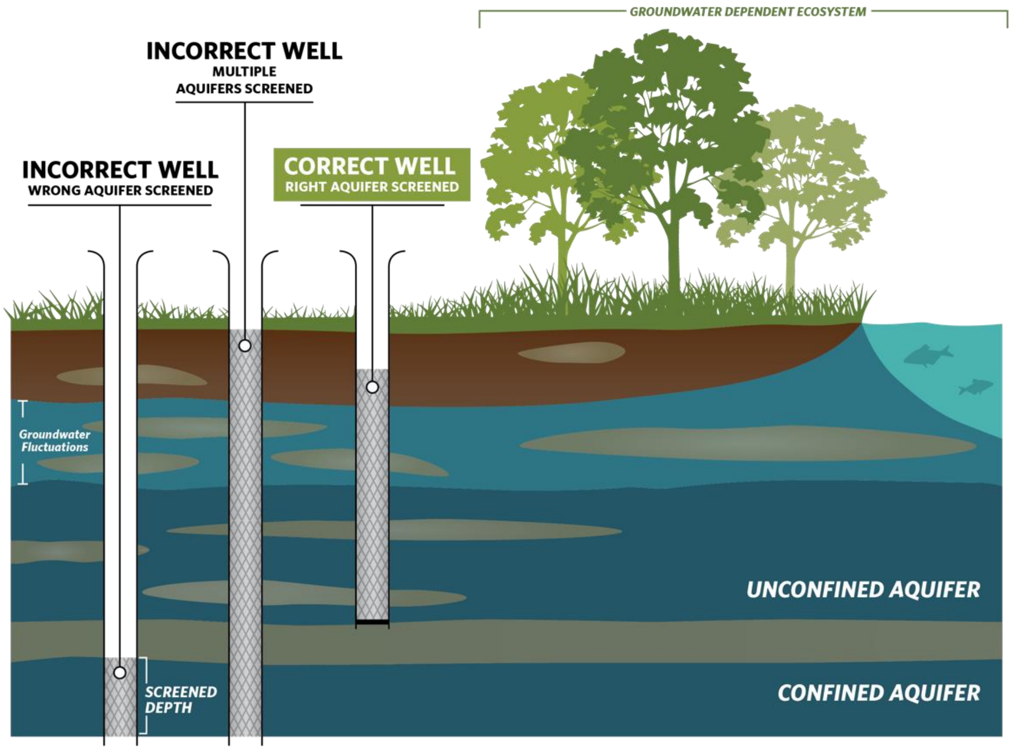

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

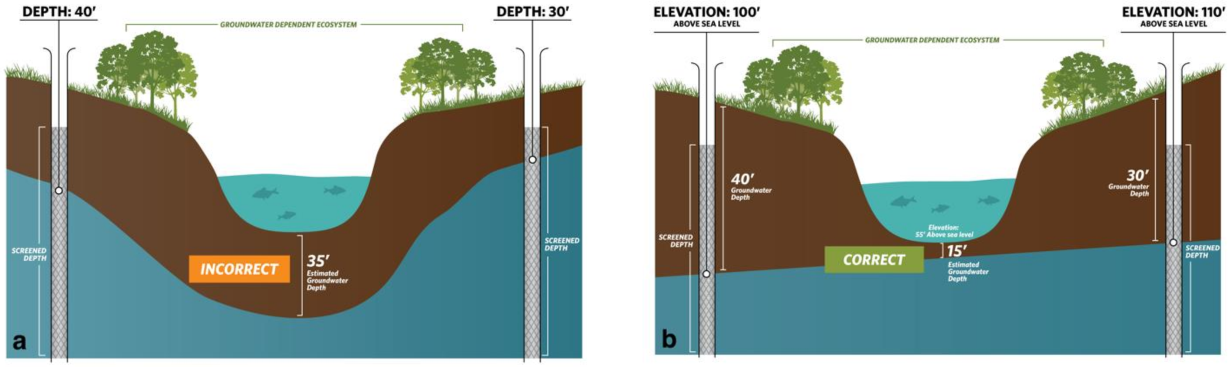

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

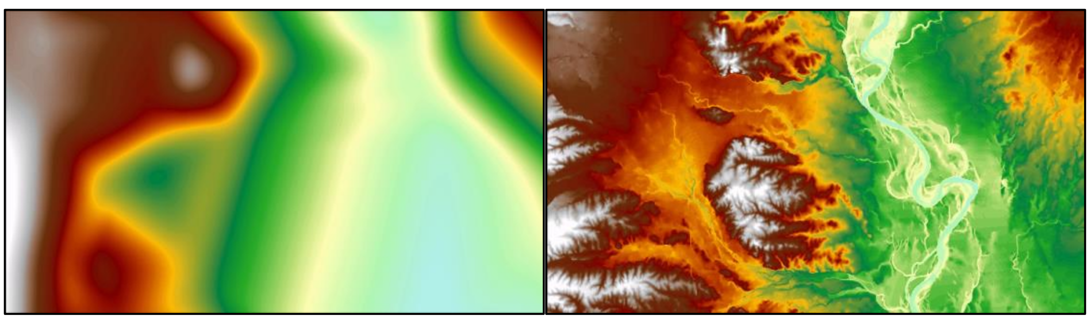

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[16] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

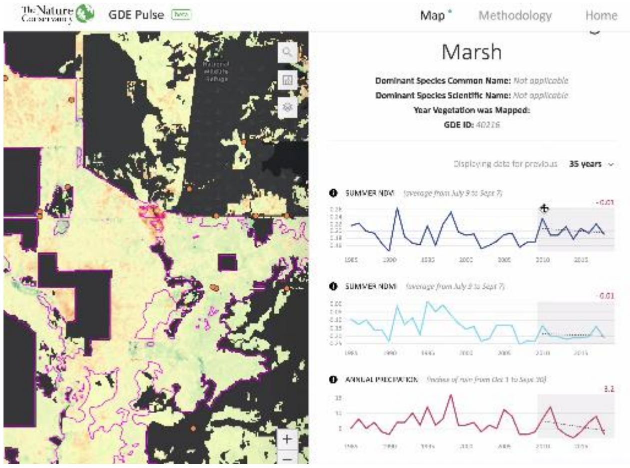
GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

[17] The Natural Communities Commonly Associated with Groundwater Dataset is hosted on the California Department of Water Resources' website: https://gis.water.ca.gov/app/NCDatasetViewer/#

Attachment G

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

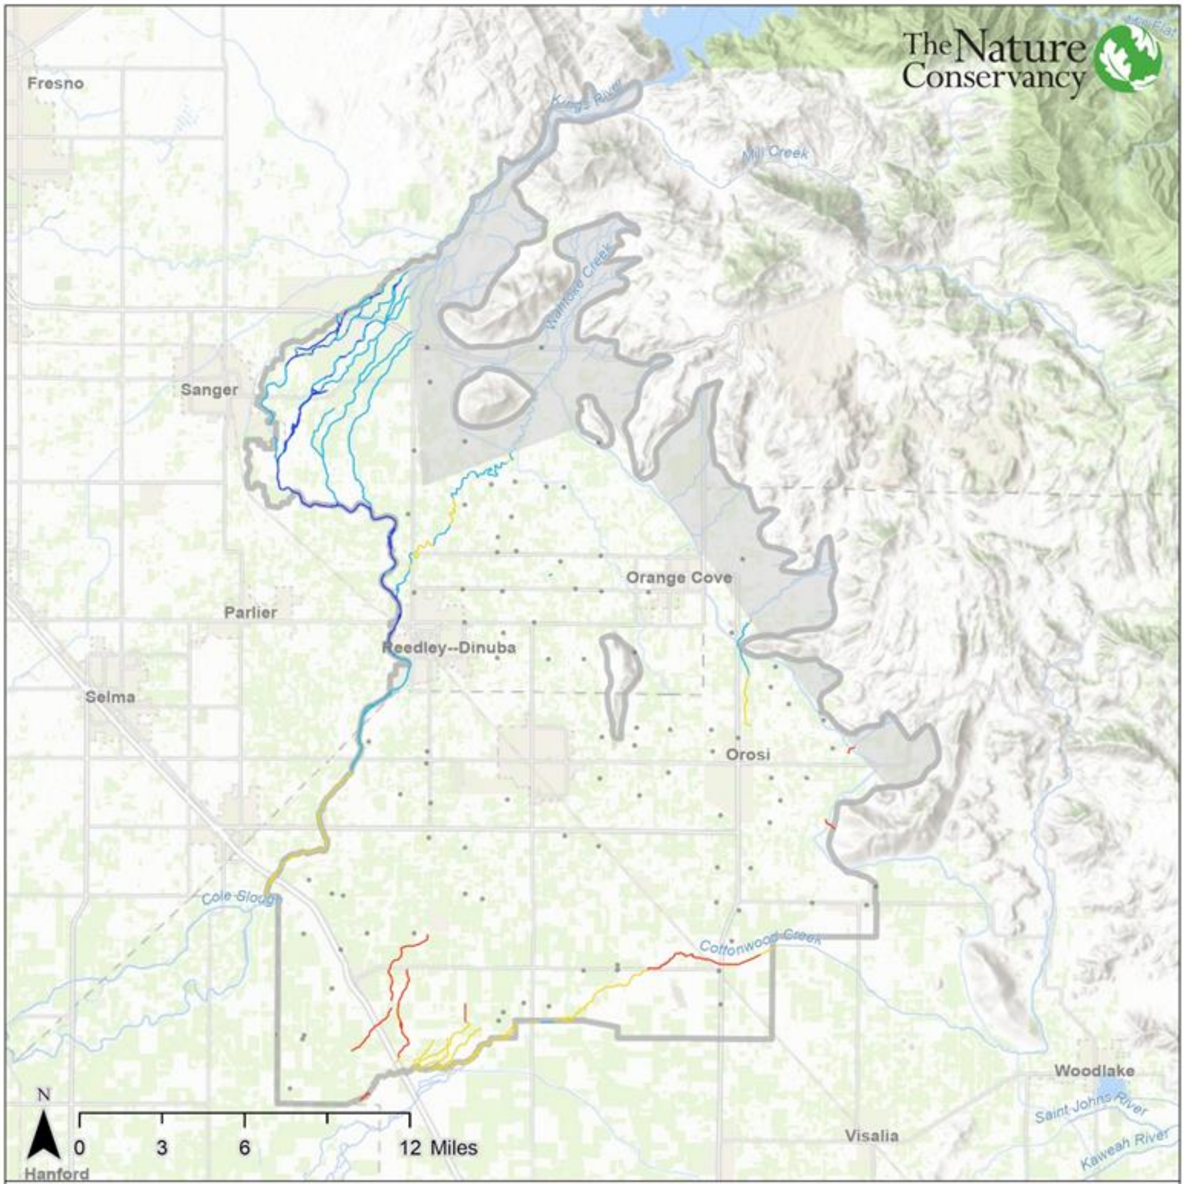
The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2011-2018)

Kings River East GSA GSP



Legend

- Groundwater Sustainability Agency (GSA)
- No groundwater depth data available
- Rivers and streams with no depth data (77.5 miles)
- Groundwater Elevation Monitoring Point

Minimum Groundwater Depth

- Connected - Gaining: Groundwater at or above stream surface (17.8 miles)
- Connected - Losing: Groundwater within 20 feet of stream surface (51.5 miles)
- Uncertain*: Groundwater within 20-50 feet of stream surface (28 miles)
- Likely Disconnected*: Groundwater greater than 50 feet below stream surface (13.4 miles)

**Streams could be connected to riparian or perched aquifers or shallow aquifers that are poorly characterized. More data are needed to confirm disconnected status.*

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Lower Tule River Irrigation District Groundwater Sustainability Plan (GSP)

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Lower Tule River Irrigation District Groundwater Sustainability Agency's (GSA's) Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be incomplete in addressing environmental beneficial uses and users. While the GSP addressed environmental beneficial users in some respects, our review finds that portions of the GSP should be remedied before being approved. Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address gaps within 180 days. In these cases, we strongly recommend that the Department set clear expectations that these be corrected in the 2025 plan update, and to the degree that gaps are due to lack of data, that these data gaps be addressed to inform the 2025 update.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as none of the 27 comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

TNC recommendation: We strongly recommend that the GSA prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP simply states that "*there is no indication of interconnected surface water systems within the Tule Subbasin*" while no monitoring data, analysis, or other information is provided to support this conclusion. The GSP also lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)).

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 952 acres of potential GDEs occur in the GSA boundary. TNC developed the Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not adequately identify, map and consider GDEs. We believe that this does not meet plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on the following:

- GDEs were rejected on the basis that groundwater levels were greater than 30 feet at a single point in time. This is a technically incorrect approach since groundwater levels fluctuate over

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30-ft or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unprotected in the GSP.

TNC recommendation: We request that the GSA use groundwater levels that represent interannual and inter-seasonal variability and utilize additional information provided in Attachment D which provides best practices for using the NC Dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and/or managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). Evapotranspiration is included in the surface water budget as a surface water outflow, but groundwater outflow to ET should also be identified as a groundwater budget component. In addition, a single ET value lumps together crops as well as native vegetation. This is problematic because key environmental uses of groundwater are not specifically being accounted for as water supply decisions are made using this budget nor will they likely be considered in project and management actions.

TNC recommendation: As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

The Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. Potential ISWs and GDEs are located in areas where no shallow groundwater monitoring currently exists or is proposed, leaving data gaps unfilled. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Attachment A

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Lower Tule River Irrigation District Groundwater Sustainability Plan

The complete LTRID GSA's GSP available at http://www.ltrid.org/sgma/#gsp for public review and comment, adopted on January 14 2020, was reviewed by TNC. We realize that the GSAs in the Subbasin have jointly prepared a comprehensive Monitoring Plan and Basin Setting, the *Tule Subbasin Monitoring Plan* and *Tule Subbasin Setting*, as Attachments 1 and 2 to the *Tule Subbasin Coordination Agreement* (Agreement and Attachments provided as Appendix A of the GSP). Responses to comments received on the Draft GSP are provided as Appendix C of the Final GSP. The comments and responses are also provided in Attachment F of this letter. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the Tri-County Water Authority GSA during the public comment period, and states whether or not they were addressed in the Final GSP *[in green text in brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 1.5.1 Beneficial Users (p. 1-39)]

- *[Our comment was not addressed. No changes to GSP text made.]* We appreciate that the GSP acknowledges that beneficial users include aquatic ecosystems associated with rivers and streams. This section could be improved by the identification of **various environmental uses and users of groundwater in the LTRID Plan Area, including: GDEs, interconnected surface waters (ISWs), managed wetlands, Protected Lands including conservation areas and other protected lands, and Public Trust Uses including wildlife (e.g., Pixley National Wildlife Refuge), aquatic habitat, fisheries and recreation, and please take particular note of the species with protected status.** The following resources can be used:
    - Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/
    - The list of freshwater species located in the Tule Subbasin in Attachment C of this letter.
    - The California Department of Fish and Wildlife's California Natural Diversity Database (CNDDB).
    - The United States Fish and Wildlife Service's ECOS mapper for critical habitat designations - https://fws.maps.arcgis.com/home/webmap/viewer.html?webmap=9d8de5e265ad4fe09893cf75b8dbfb77

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8)

[Section 1.4 LTRID GSA Plan Area (pp. 1-5 to 1-38)]

- *[No response was required.]* We appreciate that the GSP provides a description of the jurisdictional boundaries, existing land use designations, water use sectors and types, groundwater well density, and existing water use management and monitoring programs. Surface water quality monitoring is conducted in the Tule Basin Water Quality Coalition (TBWQC) area along three natural waterways including the Tule River, Deer Creek, White River, and in Porter Slough.

[Section 1.4.12 Land Use Plans (pp. 1-26 to 1-35)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The GSP describes the *General Plan for Tulare County*, and local land use plans for the Tipton, Poplar-Cotton, and Woodville Communities, which are focused on land use and water resources and supply. The GSP states (p. 1-34) that the Tulare County water resources goal is to "*provide a sustainable, long-term supply of water resources to meet domestic, agricultural, industrial, and recreational needs*." This section could be improved by providing a discussion of General Plan goals and policies related to the protection and management of wetlands, aquatic resources and riparian vegetation that could be affected by groundwater withdrawals. **Please consider adding a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs, if applicable.**
- *[Minor changes to GSP text were made but did not adequately address the comment.]* This section could be further improved by also identifying Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin that may be associated with GDE or ISW habitats. **Please consider identifying relevant HCPs and NCCPs within the GSP area, and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**

[Section 1.4.15 Summary of Well Permitting Process (pp. 1-35 to 1-36)]

- *[Our comment was not addressed. No changes to GSP text made.]* Section 1.4.15 references the Tulare County well permitting program, administered by the Tulare County Environmental Health Services Division, which issues permits to construct, reconstruct, and destroy water wells under the Tulare County Well Ordinance. **Please provide details of this program and discuss 1) its potential effects on aquifer systems 2) how future well permitting and well construction will be coordinated with the GSP to assure achievement of the Plan's sustainability goals, and 3) the well permitting process incorporates protection of GDEs and ISWs within the Subbasin.**

- *[Our comment was not addressed. No changes to GSP text made.]* The State Third Appellate District recently determined that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and

Siskiyou County, No. C083239). **Please include a discussion of the need for well permitting programs to comply with this requirement.**

Checklist Items 5 to 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 2.2.3 Bottom of Basin (p. 2-3)]

- *[Our comment was not addressed. No changes to GSP text made.]* Section 2.2.3 of the GSP and Section 2.1.4 of the *Tule Subbasin Setting* (Appendix A of the GSP) discuss the bottom of the Subbasin using two approaches: geochemical (e.g., TDS of 2,000 mg/L), and geologic (e.g., contact between the Tertiary sedimentary deposits and granitic bedrock). Defining the bottom of the basin based on geochemical or physical properties is a suitable approach for defining the base of freshwater; however, as noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions." Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom. This will prevent the possibility of extractors with wells deeper than the basin boundary (defined by the base of freshwater) from claiming exemption of SGMA due to their well residing outside the vertical extent of the basin boundary. The vertical extent of the plan area could be better described by characterizing groundwater well extractions from the deepest wells in relation to defining the basin bottom.

[Section 2.2.6 Principal Aquifer and Aquitards (pp. 2-5 to 2-7)]

- *[Our comment was not addressed. No changes to GSP text made.]* Section 2.2.6 (p. 2-5) and Section 2.1.7 of the *Tule Subbasin Setting* (Appendix A of the GSP), describe two principal aquifers: the upper and lower aquifers, which are separated by the Corcoran Clay. Section 2.2.6.5 (p. 2-7) describes the "*predominant beneficial uses of groundwater in the Subbasin as agricultural irrigation, with other beneficial uses including municipal water supply, private domestic water supply, and livestock washing and watering*." **Please describe the role of the principal aquifer(s) in supplying groundwater to all beneficial uses and users of groundwater (including environmental).**

- *[Our comment was not addressed. No changes to GSP text made.]* Although the characteristics and physical properties are well described in the *Tule Subbasin Setting* (Appendix A of the GSP), knowledge of the hydraulic interaction between the shallow and deep aquifer (refer to Section 2.1.8 of the *Tule Subbasin Setting*) is listed as one of the "*primary sources of uncertainty*" in the hydrogeologic conceptual model. However, later on the report states (p. 16, Section 2.2.1 in the *Tule Subbasin Setting*), that "*comparisons of hydrographs from wells perforated in the upper aquifer with wells perforated predominantly in the lower aquifer and in close proximity show that groundwater levels in the upper aquifer are higher than groundwater levels in the lower aquifer…. This indicates a downward hydraulic* *gradient and indicates that the upper aquifer is recharging the lower aquifer of the Tule Subbasin*." Since vertical groundwater gradients between the upper and lower aquifers and other data to describe the interaction between these aquifers are uncertain, this is considered a data gap and the *Tule Subbasin Monitoring Plan* (Appendix A of the GSP) provides a plan for installation of additional wells in both the upper and lower aquifers as well as nested wells. However, the plan does not specifically state that data collection from these new wells will be used to address data gaps regarding vertical groundwater gradients and the interaction between the upper and lower aquifers. **Since the interaction between aquifers and the potential extent of connectivity is fairly unknown, this section could be improved by adding additional information about the objectives of the proposed new wells in the *Tule Subbasin Monitoring Plan* and *Tule Subbasin Setting* and in appropriate sections of the GSP.**

[Section 2.2.1 Groundwater Occurrence and Flow (Appedix A, pp. 16)]

- *[Our comment was not addressed. No changes to GSP text made.]* Groundwater elevation contours (with respect to sea level) are shown for spring and fall 2017 (Figures 2-17 and 2-18) for the upper aquifer and for fall 2010 (Figure 2-19) for the lower aquifer. The presence or absence of shallow perched groundwater that may be in communication with GDEs and ISWs, particularly in the vicinity of the Tule River, North Tule River and various recharge ponds, is not discussed. **Please investigate whether there are any data for shallow or perched groundwater on which GDEs and ISWs may be reliant. If these data are not available, this should be identified as a data gap, and a plan for additional data collection to address the data gap should be provided in this GSP.**

[Sections 2.2.6.4 and 2.3.4 Groundwater Quality (p. 2-6, 2-9)]

- *[Our comment was not addressed. No changes to GSP text made.]* As described in Section 2.2.4 of the *Tule Subbasin Setting* (Appendix A of the GSP), the primary groundwater quality issues that could affect the beneficial uses of groundwater in the Subbasin are nitrate and pesticides. Water quality may affect GDEs and the species they support. **Please consider including data about water quality in the zones where GDEs are potentially present. If there are no data, then please recognize this as a data gap and state that additional data will be collected and analyzed.**

<u>Checklist Items 8 to 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)</u>

[Section 2.3.6 Interconnected Surface Water Systems (p. 2-10)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. ISWs can be either gaining or losing. The GSP states (p. 2-10) that "*there is no indication of interconnected surface water systems within the Tule Subbasin*." No monitoring data, analysis, or other information is provided to support this important conclusion, which suggests that this is a data gap. **Please provide data or analysis to support this statement; and identify data gaps (e.g., lack of shallow or nested/clustered monitoring wells or stream gages), reconcile them or provide a plan to address them as needed to improve identification of ISWs prior to disregarding them in the GSP.**

Checklist Items 11 to 15 – Identifying and Mapping GDEs (23 CCR §354.16)

[Sections 1.4.8.1 Potential Groundwater Dependent Ecosystems (p. 1-19) and 2.3.7 Groundwater Dependent Ecosystems (p. 2-10)]

- *[Our comment was not addressed. No changes to GSP text made.]* Section 1.4.8.1 and accompanying map (Figure 1-10) present an analysis that GDEs are shown to potentially occur along the natural reaches of the Tule River. We appreciate the use of this approach which was developed using the DWR NC Dataset Viewer Map application. It shows GDEs in a small area near the northern boundary of the LTRID Plan Area and in a larger area along the Tule River in the western portion of the Plan Area. However, in Section 2.3.7 (p. 2-10), the GSP does not acknowledge the potential GDEs, and states "*Groundwater Dependent Ecosystems are discussed in Chapter 2.2.8 [2.2.7] of the Tule Subbasin Setting, which provides justification for ecosystems within the Tule Subbasin to be identified as not groundwater dependent given that the average depth to groundwater relative to the root zone for groundwater dependent plants is well below those plants' roots systems*." In Section 2.2.7 of the *Tule Subbasin Setting* we appreciate the reference to the GDE database (www.groundwaterresourcehub.org) and the inclusion of Valley Oak root zones, which can reach a depth of approximately 25 feet. However, other phreatophytes, such as cottonwoods, can root to much deeper depths depending on the water table and presence of root restrictive layers. The depth to groundwater map shown (Figure 2-26) is based on water levels in January 2015, during the drought. We appreciate that the *Tule Subbasin Setting* does note (p. 19 of Appendix A) that there may be periods of time when the groundwater level is within 25 feet of the land surface in some areas of the Subbasin. The areas most likely to support groundwater-dependent ecosystems are along the Tule River in and upstream of Porterville, and in the upper reaches of Deer Creek and White River.
    - While depth to groundwater levels within 30 feet are generally accepted as being a proxy for deciding if polygons in the NC dataset are connected to groundwater, seasonal and interannual groundwater fluctuations in the groundwater regime must be taken into consideration. Utilizing groundwater data from one point in time (e.g., winter 2014 to 2015, during the height of the recent drought) can misrepresent groundwater levels near GDEs and whether groundwater is available to meet their water requirements, and result in adverse impacts to the GDEs. Based on a study we recently

submitted to *Frontiers in Environmental Science*, we've observed riparian forests along the Cosumnes River to experience a range in groundwater levels between 1.5 and 75 feet over seasonal and interannual timescales. Seasonal fluctuations in the regional water table can support perched groundwater near an intermittent river that seasonally runs dry due to such fluctuations. While truly perched groundwater itself cannot directly be managed due to its isolation in the vadose zone, the water table position within a continuous saturated zone connected to the upper regional aquifer can and should be monitored and managed. **Depth to groundwater contour maps should be included in the GSP for the uppermost shallow groundwater system, if present, in the vicinity of the Tule River.** We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons to support determination whether they are groundwater dependent. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer**. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset seasonally and interannually, or to determine conclusively whether shallow groundwater is hydraulically connected to underlying aquifers, include those polygons in the GSP until data gaps are reconciled in the monitoring network, and include specific measures and time tables to address the data gaps.**

- **Please provide depth to groundwater contour maps and note the following best practices for doing so.**
  - Are the wells used for interpolating depth to groundwater sufficiently close (<5 km) to NC Dataset polygons to reflect local conditions relevant to ecosystems?
  - Are the wells used for interpolating depth to groundwater screened within the surficial unconfined aquifer and capable of measuring the true water table?
  - Is depth to groundwater contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape? This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to contour depth to groundwater.

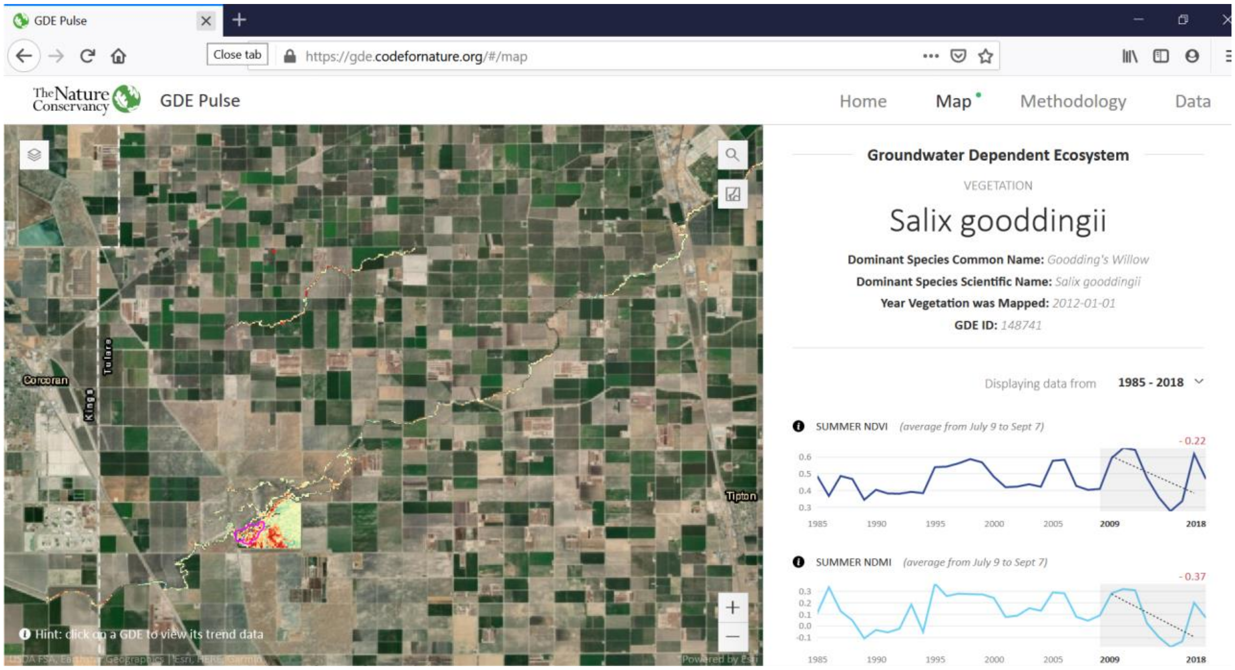
- There are not many existing wells completed in the upper aquifer (refer to Figure A1-2 in the *Tule Subbasin Monitoring Plan)* within the northern portion of the LTRID Plan Area in the vicinity of the Tule River and the mapped GDEs (Figure 1-10, Potentially Groundwater Dependent Ecosystems in the LTRID GSA Area). If there are insufficient groundwater level data in the upper aquifer and potential overlying shallow groundwater zones, then the NCCAGs in these areas should be included as potential GDEs in the GSP until data gaps are reconciled in the monitoring network. Confirmation of GDEs should be based on depth to groundwater in the shallow zone, or a correlation of groundwater depth and remote sensing data. **Please revise the GDE analysis in the GSP to include a complete analysis and identification of data gaps.**
- Groundwater requirements of GDEs vary with vegetation types and rooting depths. **Please indicate what vegetation is present in the potential GDEs, and whether the GDE was eliminated or retained based solely on the 30-foot depth limit.** While Valley Oak (*Quercus lobata*) have been observed to have a maximum rooting depth of ~24 feet rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant.

- *[Our comment was not addressed. No changes to GSP text made.]* In the scientific literature, it is generally acknowledged that GDEs can rely on groundwater for some or all of their requirements. GDEs can rely on multiple water sources simultaneously and at different temporal and / or spatial scales (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow), and yet still require groundwater in order to remain viable and healthy. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface". The operative consideration in this definition is dependence, not exclusive dependence or continuous connection. Hence, we recommend using depth to groundwater contour maps derived from subtracting groundwater levels from a DEM, as described above, to identify whether a connection to groundwater exists for the GDEs presented in Figure 1-10. **Please refer to Attachments D and E of this letter for best practices for using local groundwater data to 1) verify whether polygons in the NC Dataset are supported by groundwater in an aquifer, and 2) verify whether ecosystem decline or recovery is correlated with groundwater levels.**

<u>Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)</u>

[Section 2.3.7 Groundwater Dependent Ecosystems (p. 2-10)]

- *[Our comment was not addressed. No changes to GSP text made.]* **Please provide information on the historical and current groundwater conditions near potential GDEs and / or the ecological conditions present during these times**. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data remote sensing data (e.g., NDVI, leaf area index, evapotranspiration [ET] or other data) to describe depth to groundwater trends in and around GDE areas, and how they relate to trends in plant growth and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the Subbasin.



- **Please consider an ecological inventory for potential GDEs (see Appendix III, Worksheet 2 of the GDE Guidance) that includes vegetation or habitat types that ranks the GDEs as having a high, moderate or low value.**

- **Please consider identifying whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat have been identified in or near any of the GDEs.** Resources for this include the list of freshwater species located in the Subbasin that can be found in Attachment C of this letter, the Critical Species Lookbook, USFWS' ECOS mapping tool, and CDFW's CNDDB database.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 2.4 Water Budget (pp. 2-11 to 2-27)]

- *[Our comment was not addressed. No changes to GSP text made.]* ET is included in the surface water budget as a surface water outflow (Section 2.3.1.2 of the *Tule Subbasin Setting, Appendix A of LTRID GSP*) and is assumed to be the balance between total precipitation and areal recharge (p. 30 of Appendix A). The GSP (p. 30 of Appendix A) states that the ET "*value includes evapotranspiration from crops as well as native vegetation*" (ET value listed on Table 2-2b of Appendix A). However, crops and native vegetation are lumped together as a single ET value. Groundwater outflow to ET should also be identified as a groundwater budget component. If the outflow is not known, it should be identified as a data gap and provisional information should be provided until an analysis can be performed to address the data gap. **Please provide a breakdown of ET for riparian and other native vegetation (such as wetlands, marshes, phreatophytes and other communities). Identify any data gaps and outline the actions needed to address them and the schedule for their implementation.**

Checklist Item 23-26 Sustainability Goal (23 CCR §354.24)

[Section 3.2 Sustainability Goal (p. 3-1)]

- *[Our comment was not addressed. No changes to GSP text made.]* The Sustainability Goal of the Tule Subbasin GSAs is "*the absence of significant and unreasonable undesirable results associated with groundwater pumping, accomplished by 2040*." A further goal is that coordinated implementation of their respective GSPs "*will achieve sustainability in a manner that facilitates the highest degree of collective economic, societal, environmental, cultural, and communal welfare and provides all beneficial uses and users the ability to manage the groundwater resource at least cost*." **We appreciate the inclusion of environmental uses and users of groundwater in the Sustainability Goal. We suggest adding a reference to GDEs and ISWs, which may be present in the Subbasin (please see comments under Checklist Items 16-20) and are beneficial users of groundwater.**

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP states that there is no connectivity between groundwater and the Tule River; however, there isn't quantitative analysis, monitoring data, or other information provided to support this finding. **Please include ISWs in the Sustainability Goal until sufficient data is available to conclude the status of ISWs.**

- *[Our comment was not addressed. No changes to GSP text made.]* GDEs are dependent, in part, on suitable water quality; however, the GSP only considers water quality for irrigation and domestic use. **Please include impacts from degraded water quality on the plant and wildlife communities within GDEs**.

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Section 3.5.1 Measurable Objectives and Interim Milestones (pp. 3-5 to 3-14)]

- *[Our comment was not addressed. No changes to GSP text made.]* Interim milestones and measurable objectives for the chronic lowering of groundwater levels, groundwater storage, and degraded groundwater quality sustainability indicators do not mention environmental users, such as GDEs and ISWs. For each of these applicable sustainable management criteria, **please include a discussion of ISWs and GDEs in this section and state whether the measurable objectives and interim milestones will help achieve the Sustainability Goal.**

- *[Our comment was not addressed. No changes to GSP text made.]* Section 3.4 (p. 3-3) states that the depletion of ISWs does not apply as a sustainability indicator, and therefore, "*cannot create adverse conditions that are significant and unreasonable*." No monitoring data, analysis, or other information is provided to support this important conclusion, which suggests that this is a data gap. **Please modify this section of the GSP to 1) develop measurable objectives for possible ISWs, including GDEs, and 2) include a statement that a data gap exists related to the interconnectedness of the Lower Tule River, White River and Deer Creek with shallow groundwater.**

<u>Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.26c</u>)

[Section 3.5.2 Minimum Thresholds (pp. 3-14 to 3-20)]

- *[Our comment was not addressed. No changes to GSP text made.]* Similar to the discussion of measurable objectives and interim milestones, minimum thresholds for chronic groundwater level decline, storage depletion and groundwater quality do not consider GDEs, and minimum thresholds for depletion of ISWs are not developed. **Please include development of sustainable management criteria for GDEs and ISWs as discussed above.**

<u>Checklist Item 30-46 – Undesirable Results (23 CCR §354.26</u>)

[Section 3.4 Undesirable Results (p. 3-2)]

- *[Our comment was not addressed. No changes to GSP text made.]* Undesirable results are not described in the GSP. Section 3.4 refers readers to the *Tule Subbasin Setting Coordination Agreement* (Appendix A of the GSP). Undesirable results are not described in the coordination agreement either. The GSP (p. 3-3) states that there are four groundwater conditions with sustainability indicators that may have potential to cause significant and unreasonable effects within the Subbasin. These conditions are 1) chronic lowering of groundwater levels indicating a depletion of supply if continued over the planning and implementation horizon; 2) reduction of groundwater storage; 3) Degraded water quality, including the migration of contaminant plumes that impair groundwater supplies; and 4) land subsidence that substantially impacts critical infrastructure. The GSP states (p. 3-3) that "*…to groundwater conditions, the depletion of interconnected surface waters and seawater intrusion, do not apply as sustainability indicators within the Tule Subbasin, and therefore, cannot create adverse conditions that are significant and unreasonable*." However, no monitoring data, analysis, or other information is provided to support this important conclusion. **Please modify this section of the GSP to describe undesirable results for the four groundwater conditions with sustainability indicators addressed and add the depletion of ISW sustainability indicator. Please include a discussion of potential ISWs and GDEs.**

<u>Checklist Items 47-49 – Monitoring Network (23 CCR §354.34)</u>

[Chapter 4 Monitoring Network (p. 4-2)]

- *[Our comment was not addressed. No changes to GSP text made.]* As described in Section 4.1 (p. 4-2), the GSAs in the Subbasin have prepared a coordinated monitoring plan, the *Tule Subbasin Monitoring Plan*, provided as Attachment 1 to the Tule Subbasin Coordination Agreement (Appendix A of the GSP). The GSP summarizes the Subbasin monitoring network by referencing the *Tule Subbasin Monitoring Plan* and providing any additional information that directly relates to the LTRID GSA's monitoring network for each sustainability indicator. In the monitoring well design section, the GSP states (p. 4-3) that *"…the sustainability indicators of seawater intrusion and depletion of interconnected surface water are not applicable to the Tule Subbasin*." No monitoring data, analysis, or other information is provided to support this important conclusion, which suggests that this is a data gap. **Please provide data or analysis to document this statement.** As stated above in the comments for Checklist Items 8-20, **please reconcile data gaps (shallow monitoring wells, stream gages, and nested/clustered wells) in this section of the GSP to improve ISW characterization in future GSPs.**

- *[Our comment was not addressed. No changes to GSP text made.]* Representative monitoring (p. 4-6) accounts for the five management areas established in this plan (jurisdictional boundaries of the Lower Tule River Irrigation District, Tipton Community Service District, Woodville Public Utility District, Poplar Community Service District, and the County MOU area within Tulare County) and consists of 10 wells for monitoring groundwater levels (Table 4-1, p. 4-8) and six wells for monitoring groundwater quality (Table 4-2, p. 4-10). To address the groundwater level data gaps, new monitoring well locations have been identified for monitoring the individual aquifers in the Subbasin in areas where there are no existing wells, as described in Section 2.1.1.1 (p. 6) of the *Tule Subbasin Monitoring Plan* (Appendix A of the GSP). The plan states that the new wells, combined with existing monitoring wells, will improve the ability to develop representative upper aquifer groundwater contour maps and provide a better network of calibration targets for the Subbasin-wide groundwater model. A total of 12 new upper aquifer monitoring wells have been identified for possible inclusion in the plan as shown on Figure A1-2 of the *Tule Subbasin Monitoring Plan* (Appendix A of the GSP). Of these wells, four will be completed as stand-alone upper aquifer monitoring wells and eight will be completed as nested wells with separate casings perforated in the upper and lower aquifers. One proposed well (Well 4) is located in the vicinity of GDEs near the northern boundary of the LTRID Plan Area (Figure 1-10) (refer to comments above for Checklist Items 11-15). However, there are no proposed well locations near the larger GDE area along the Tule River in the western portion of the Plan Area. Since the upper aquifer is the groundwater that would most likely be connected to GDEs and ISWs, the network should include monitoring wells in this zone near the areas where GDEs have been mapped**. We suggest modifying the well network to monitor the shallow zone near GDEs and ISWs.**

Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Chapter 5 Projects and Management Actions (pp. 5-1 to 5-30)]

- *[Minor changes to GSP text were made but did not adequately address the comment.]* Chapter 5 identifies many important projects including LTRID GSA groundwater accounting actions, existing water supply optimization projects, surface water development projects, managed aquifer recharge and banking projects, and agricultural land retirement projects). These projects generally benefit the groundwater elevations, groundwater storage, groundwater quality, and land subsidence sustainability indicators. Surface water development projects that increase the total volume of water dedicated toward groundwater recharge, and construction or expansion of recharge pond projects may have potential environmental benefits. It would be advantageous to demonstrate multi-benefit projects from a funding and prioritization perspective.
    - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
    - If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting ISWs and GDEs.**
    - The surface water development / storage projects, such as the Success Reservoir Enlargement Project (p. 5-14) and Expansion or Development of new Irrigation District Recharge Basins (p. 5-19), can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such facilities have been incorporated into local HCPs and NCCPs, more fully recognizing the value of the habitat that they provide and the species they support. **For projects that construct recharge ponds, please consider identifying if there is habitat value incorporated into the design and how the recharge ponds can be managed as multiple-benefit projects to benefit environmental users.** Grant and funding opportunities for SGMA-related work may be prioritized for multi-benefit projects that can address water quantity as well as provide environmental benefits. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**
    - For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

Attachment C

Freshwater Species Located in the Tule Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Tule Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[2]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[3] as well as on TNC's science website[4].

Scientific Name	Common Name	Legally Protected Species

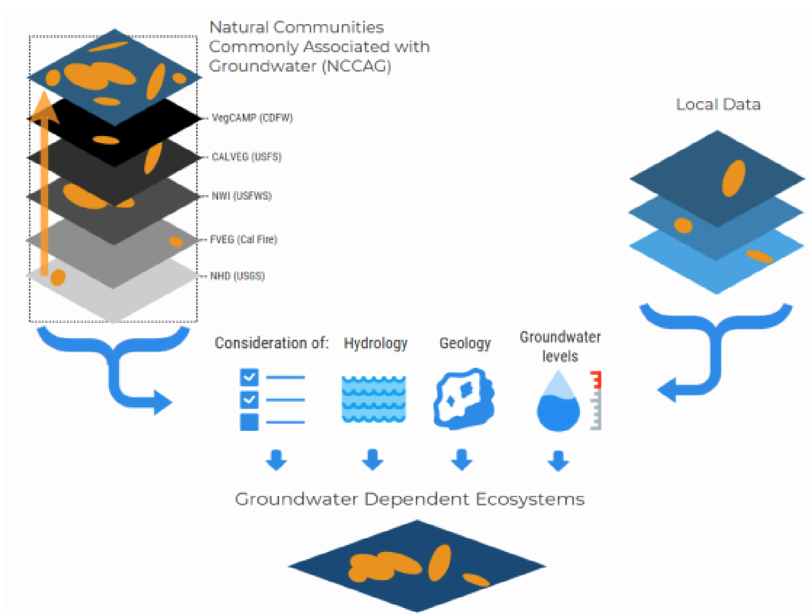
July 2019

IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[5] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[6]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[5] *NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/*

[6] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[7]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[8] on the Groundwater Resource Hub[9], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

[9] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

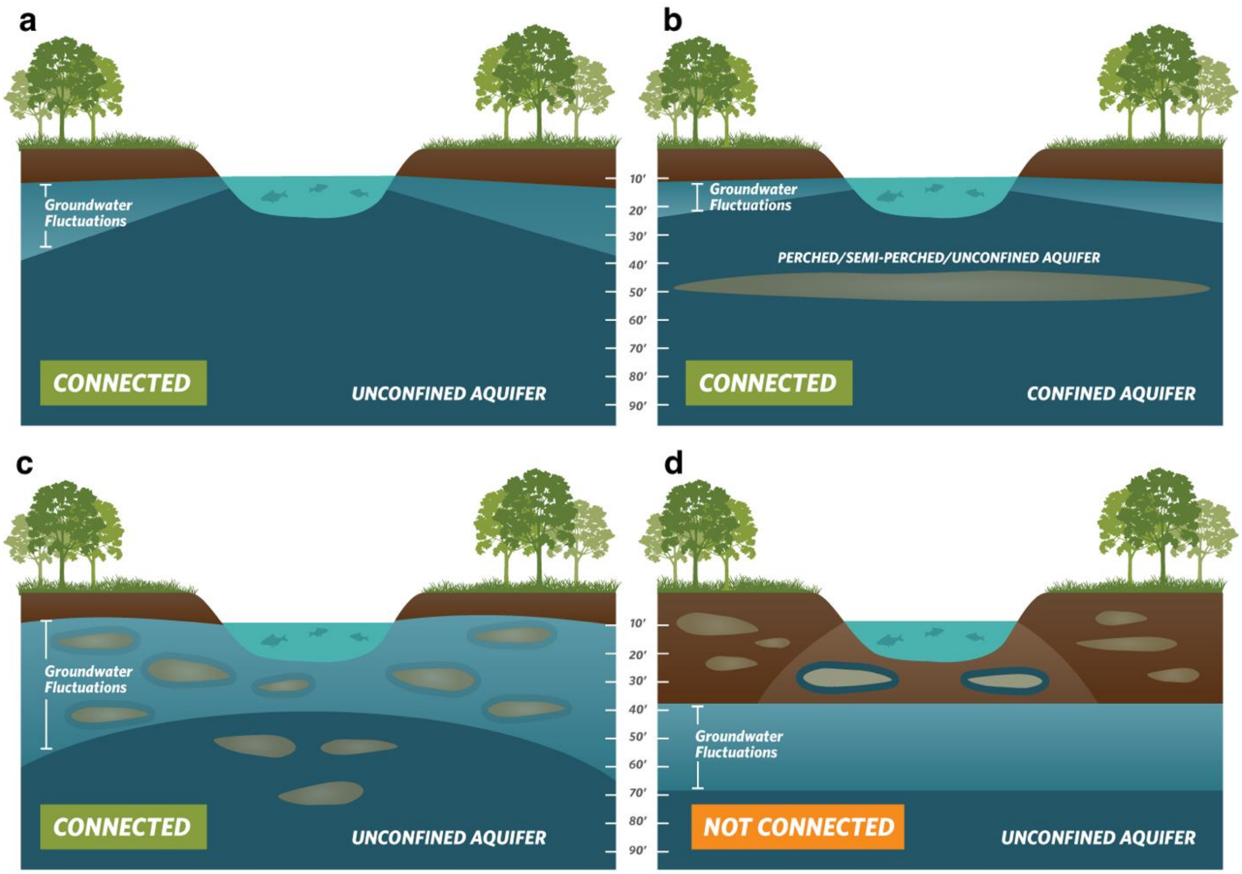

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[10] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[11] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[12] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[13]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

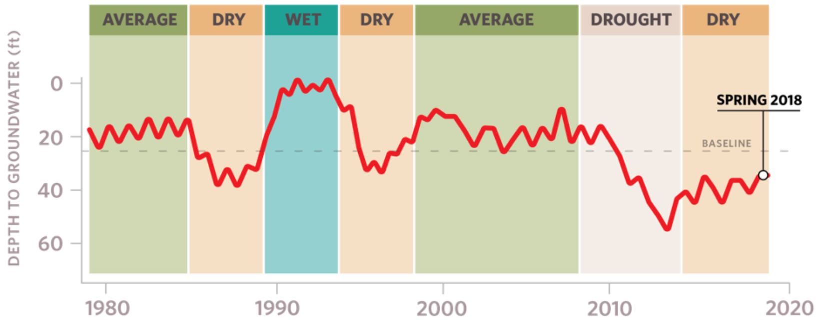

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[10] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[11] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[12] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[13] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[14], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

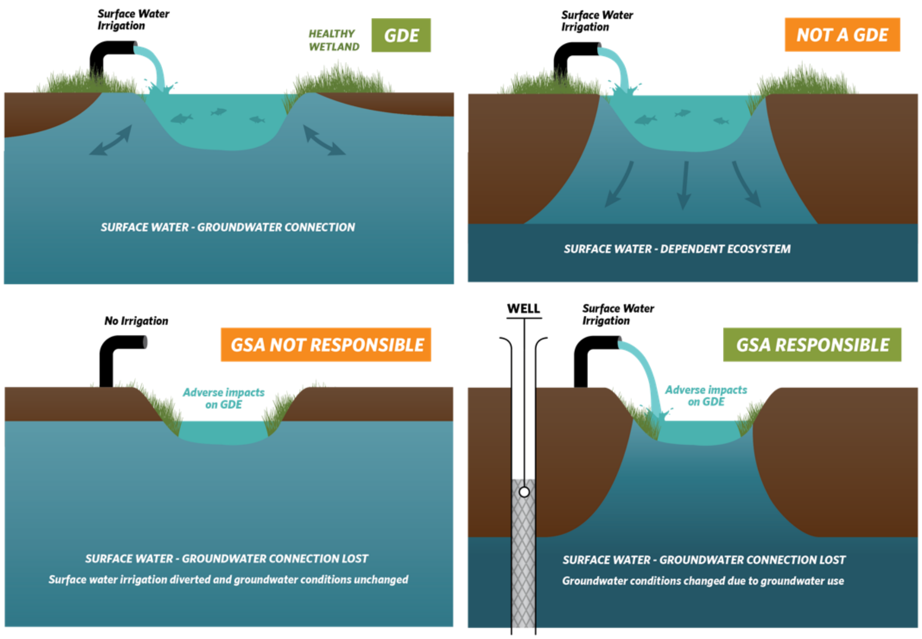

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

---

[14] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

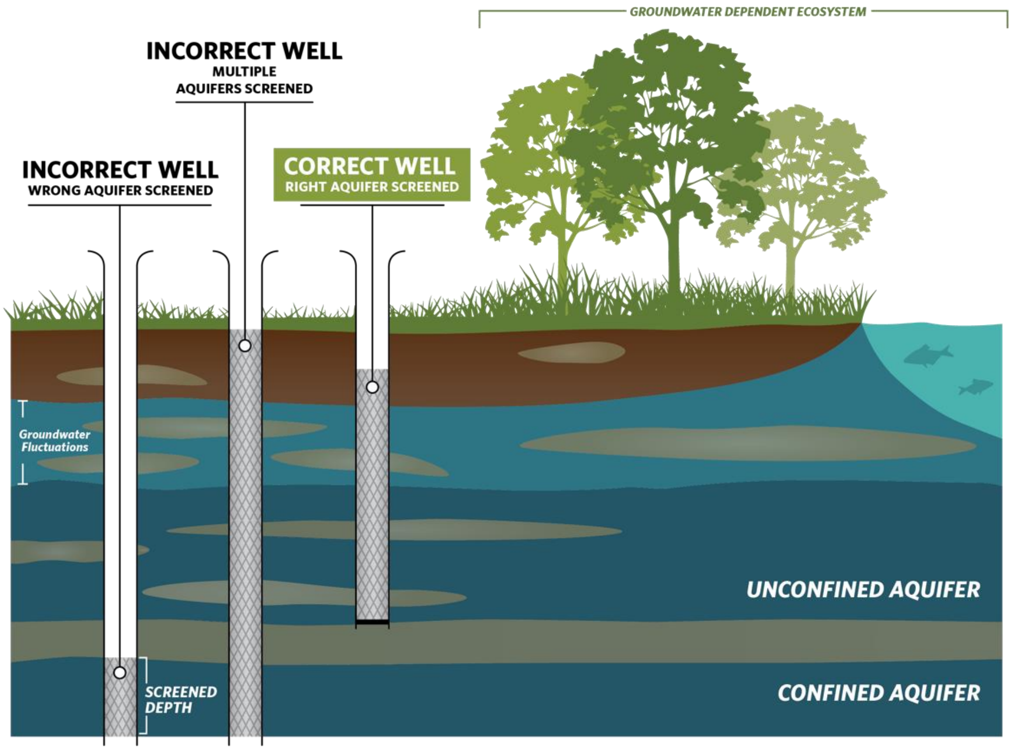

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[15] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

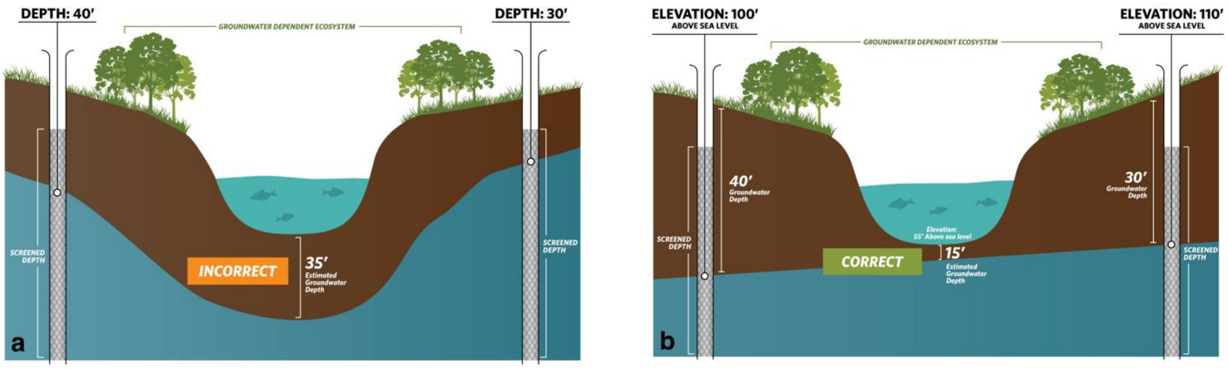

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

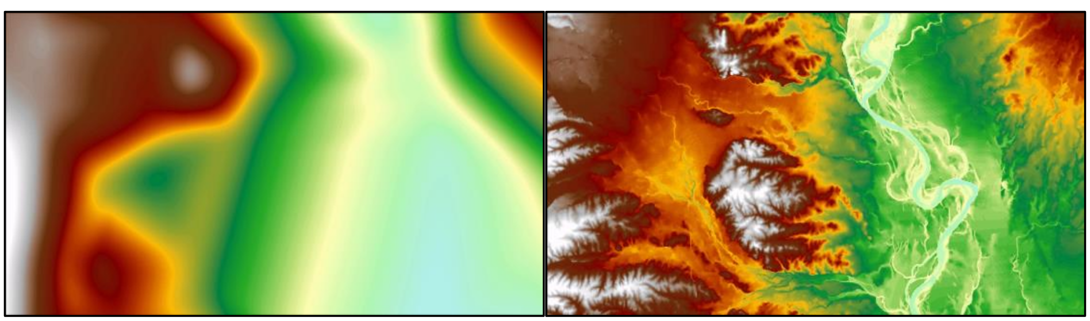

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[15] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

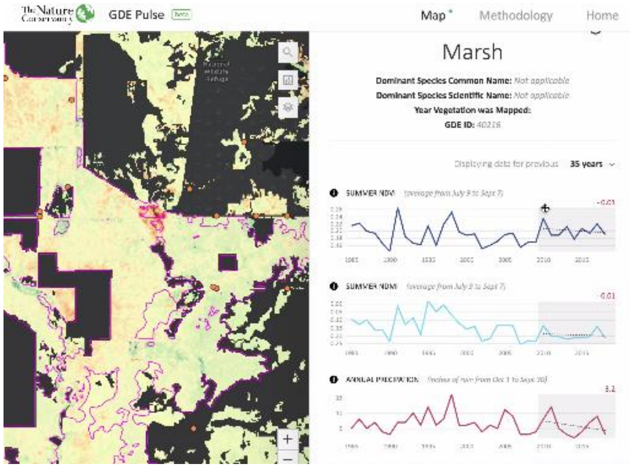
The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Attachment E

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

Visit https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[16]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[17]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

---

Attachment F
GSA Response to TNC Comments on Draft GSP

MASTER RESPONSES TO COMMENTS RECIVED BY LOWER TULE RIVER IRRIGATION DISTRICT GSA (LTRIDGSA)

The following Master Responses have been prepared by staff for consideration by the Governing Board of the LTRIDGSA. The numbered responses correspond to the topics identified on the attached Table of Comments Received:

1. **<u>SUBSIDENCE/INFRASTRUCTURE IMPACTS</u>**
   a. **COMMENTORS:**
   Friant Water Authority, Arvin-Edison Water Storage District, Shafter-Wasco Irrigation District, United States Department of the Interior – Bureau of Reclamation, Lindsay-Strathmore Irrigation District.
   b. **COMMENT SUMMARY:**
   A number of comments were received on the topic of land subsidence and related impacts to infrastructure including the Friant Kern Canal (FKC), expressing concern that continued FKC subsidence will negatively impact other FKC users and was not adequately described in the GSP, and suggesting that the minimum thresholds for land subsidence established in the GSP should be set lower.
   c. **MASTER RESPONSE:**
   The undesirable results associated with subsidence that impacts major infrastructure such as the FKC is described in detail in the GSP itself, as well as in the Coordination Agreement between the GSAs in the Tule Subbasin, and in supporting technical reports. As has been shown in numerous studies, land subsidence is a gradual process that takes time to develop and time to halt.
   Subsidence impacts from groundwater pumping that have already occurred may continue for years. The minimum thresholds identified in the GSP, which were adopted in consultation with the other GSAs subject to the Tule Subbasin Coordination Agreement, must take into consideration future subsidence caused by groundwater pumping that has already occurred, along with proposed future actions. Based on existing information available to the GSA and information provided in the comment letters , the pumping by irrigators within the GSA has not been identified as the primary cause of the FKC subsidence, and much of the subsidence has occurred due to groundwater pumping outside the GSA boundaries. The GSP includes a number of actions to reduce undesirable results within the GSA's boundaries, but cannot control actions that occur outside GSA boundaries or reverse groundwater pumping that has already occurred. By reference to

the Coordination Agreement and the technical data related to that Agreement, the GSA believes that there has been adequate description of the subsidence issues related to critical infrastructure, including specifically the FKC.

Regarding the monitoring sites (RMS) and measureable objectives and minimum threshholds selected for the Subsidence Indicator, the GSA notes that subsidence impacts to critical infrastructure, including the FKC, are still in the process of being understood and quantified. At the same time the GSA acknowledges that site-specific monitoring locations as well as higher sensitivity minimum threshholds may be warranted in specific areas, which may in the future warrant consideration of establishment of management areas for these regions. The GSA governing board may consider additional language to address this concern be added to the GSP (See staff recommendations below.)

Regarding specific mitigation measures or payments for FKC repairs, the GSP identified, in general, that transitional pumping fees and penalties for excessive water usage would be used to mitigate impacts caused by groundwater pumping above the sustainable yield of the Tule Subbasin. As identified in the GSP, these fees will be adopted during the planning period. The GSA may consider adding additional provisions of the GSP to specify that it is likely that at least a portion of those fees will be used for mitigating impacts to critical infrastructure, and that the FKC is a likely focus of any contribution of fees for mitigation purposes (See staff recommendations below).

Several comments were received noting that the GSP's description of a transitional pumping plan to reduce groundwater pumping over time could potentially allow for pumping levels above current levels if each acre within the GSA utilized the full amount of transitional pumping. The GSP is identifying, in general terms, the transitional pumping plan that will be applied between 2020-2040, and the general description of the plan includes accounting for the pumping levels throughout the GSA and calling for a general reduction in use. Specific rules for the transitional pumping will be adopted under the GSP and these rules will be drafted to ensure that that overall pumping levels will not increase under transitional pumping. Transitional pumping is intended to allow for the reduction of groundwater pumping gradually; it is not intended to allow an increase in groundwater pumping.

d. STAFF RECOMMENDATIONS

Staff recommends that additional language could be added to the following sections of the GSP:

Recommendation 1.a. End of Section 3.5.1.4.2 (Measureable Objectives and Interim Milestones/Land Subsidence/Process for Determining Measurable Obectives and Interim Milestones):

"In response to concern about subsidence-related damage specifically to the Friant-Kern Canal ("FKC"), it has been suggested that monitoring sites and higher sensitivity Minimum Thresholds should be established for areas in close proximity to the FKC. In concept, the development of a defined FKC subsidence management area within the Tule Subbasin, with specific minimum thresholds and management actions for that management area, may be appropriate for some portions of the GSA. However, this is an action that the GSA Board, as well as the governing boards of other GSAs within the Tule Subbasin, will consider in the future as regionalized subsidence impacts are better understood through future monitoring and analysis."

Recommendation 1.b. End of Section 5.2.1. (Management Actions/Agency Groundwater Accounting Action):

"*The GSA recognizes that the Friant Kern Canal ("FKC") is among the most important critical infrastructure features that has been and will continue to be affected by subsidence. Along with the other GSA's in the Tule Subbasin, the LTRIDGSA has been part of the discussions on finding solutions to mitigate for future FKC subsidence. The relationship between groundwater use specifically within the GSA's planning area and subsidence of the FKC is still being studied and developed at the Subbasin level. As the FKC subsidence mitigation issues, and the relative impact of groundwater use as amongst the various regions of the Subbasin, become better defined, the GSA may consider adopting a specific policy that calls for the use of a reasonable portion of the transitional pumping fees, or other GSA related fees, for mitigation of future FKC subsidence. At this time, however, any mitigation program is too speculative to be defined specifically in the GSP. In concept, the development of a defined FKC subsidence management area within the Tule Subbasin, with specific minimum thresholds and management actions for that management area, is an action for future consideration by the GSA Board and by the governing boards of other GSAs within the Tule Subbasin."*

2. ENVIRONMENTAL/GROUNDWATER DEPENDENT ECOSYSTEMS

a. COMMENTORS:

Audubon California / Community Water Center / The Nature Conservancy (joint letter); California Department of Fish and Wildlife; The Nature Conservancy (individual letter)

b. SUMMARY OF COMMENTS:

Several commenters suggested that the GSP did not utilize statewide data sources for identifying Groundwater Dependent Ecosystems (GDEs), and requested the GSP provide additional information concerning GDEs.

c. MASTER RESPONSE:

The term Groundwater Dependent Ecosystems has been specifically defined at 23 CCR § 351(m) to mean "ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface." The report prepared by the Tule Subbasin GSAs, the Tule Subbasin Settings referenced in section 2.3.6 of the GSP and attached to and incorporated into the GSP, found no interconnected surface water systems in the Tule Subbasin. Based on the data collected as part of the Tule Subbasin Setting no areas of surface water were found that meet the above definition.

Section 2.3.7 of the GSP, again referencing the *Tule Subbasin Settings*, found no GDEs based on a review of the the CDWR Groundwater Dependent Ecosystems database and the applicable depth to groundwater maps, although noting that such systems may be found in upstream areas of surface water streams. There may be areas where GDEs could exist due to seasonal variations, water year types, or areas where the type of soil allows slow percolation of surface waters or a perched level of groundwater, but such areas have not yet been identified from available data sources. Based on existing studies, and the nature of the groundwater basin as being clearly detached from any surface water ecological assets, it is not likely that any GDEs meeting the statutory definition exist (as noted in section 1.4.8.1 of the GSP).

The GSA will continue to address any emerging data. As the planned monitoring network is implemented and additional monitoring stations are installed and additional data is collected, particularly in areas near surface water, this analysis will be updated as data is collected. The potential for short term connectivity due to variations in water year types during different seasons of the year or due to types of soil will be studied. If interconnected surface waters or GDEs are identified, then the GSP will be updated to reflect how the identified sustainable management criteria will impact these areas.

Until there has been any new information that establishes the likelihood of the existence of any GDEs within the GSA planning area, additional information concerning the identification of conservation areas and public trust lands, as suggested by the comments received, is not warranted. If the GSA learns of the existence of areas that meet the regulatory definition of GDEs, then it will consider the list of freshwater species provided by The Nature Conservancy, and determine the appropriate measurable objectives and minimum thresholds

d. STAFF RECOMMENDATIONS

Recommendation 2.a. Staff recommends that the GSA governing board consider adding all or a portion of the above response as additional text in the GSP at the end of Section 1.4.8.1 (GSA Plan Area/Communities Dependent on Groundwater/Potentially Groundwater Dependent Ecosystems).

3. BENEFICIAL USER IDENTIFICATION - PUBLIC WATER SYSTEMS/DOMESTIC WELLS

a. COMMENTORS:

AC-CWC-TNC, CWC, TC, WPUD

b. SUMMARY OF COMMENTS:

Commenters assert that the GSP does not adequately describe public drinking water systems or Disadvantaged Communties, does not identify domestic water users or domestic well identification and quality tracking data, and does not identify how an adequate groundwater supply will be ensured for public water systems and domestic water users or future growth of those systems.

c. MASTER RESPONSE:

Regarding the assertion that public drinking water systems have not been adequately identified or included in the planning process, these comments ignore the fact that the LTRIDGSA formed under cooperative agreements with the only public water systems and Disadvantaged Communtities that exist within the GSA's planning area, with the exception of Woodville Labor Camp, which is identified in the GSP as public water system. Accordingly, the public water systems and DACs have been specifically identified from the outset of the planning process, and the DAC representatives have participated in every aspect of the GSP review process from the outset of GSP development. These representatives have had the opportunity to suggest specific monitoring steps, measurable objective criteria and management actions, but did not in fact offer any.

As described in the GSP (in particular Section 1.4.3.2), the agreements with the PUD/CSDs within the GSA boundaries (copies of signed agreements attached to the draft GSP as Appendix 1-F provide extensive detail on how the GSA has engaged, and will continue to engage, with the PUD/CSDs under SGMA. Some of the specific provisions of these agreements include:

- PUD/CSDs agreed not to form a GSA over its jurisdictional boundaries of the GSA and agreed to be included within the boundaries of the GSA
- Sections 5-7 of the MOUs between the Special Districts and the GSA provide for various terms related to accounting for PUD/CSD water use,

and potential treatment of the PUD/CSD as a separate management area.

- Sections 9-10 of the MOUs provide the PUD/CSDs with various means for participation in the preparation of the GSP, which is intended to ensure that water supply planning for their areas is adequately provided for in the GSP.
- Section 11 of the MOUs provide the PUD/CSDs with the ability to withdraw from the Agreements and constitute their own GSAs, either individually or in combination with other agencies, a provision that is intended to protect the ability of the PUD/CSDs to manage its own groundwater supply planning in the event that any of them are not satisfied with the protections provided in the GSP prepared by the Irrigation District GSA.

These provisions will be implemented through the Groundwater Accounting system described in Section 5.2.1 of the GSP. Draft policies implementing this provision of the GSP have been drafted with input from the PUD/CSDs, and will be adopted following final adoption of the GSP. These policies essentially provide that the PUD/CSDs are able to operate according to historic averages without incurring any additional fees or costs, while providing a mechanism to allow for growth through the payment of fees for exceedance of historic pumping amounts. No additional or clarifying text to the GSP will is being recommended.

Regarding individual domestic connections, the GSA acknowledges that domestic well data represents a data gap that will be addressed moving forward, and is recommending additional GSP text to address this.

d. STAFF RECOMMENDATIONS

Recommendation 3.a. Staff recommends that the GSA governing board consider adding the following text to end of Section 3.5.1.3.1 (Measureable Objectives and Interim Milestones/Groundwater Quality/Process for Determining Measurable Obectives and Interim Milestones).

The GSA acknowledges a gap in data related to individual domestic well water locations, elevations and water quality. The GSA will address this gap in coordination with Tulare County, to the extent it is not addressed by other water quality monitoring programs that are being coordinated with this GSP. Although the GSA cannot assume responsibility for failure of individual wells, the GSA may consider additional management actions beyond those identified in Section 5 of this GSP if specific data is developed that identifies domestic wells that go dry due to the lowering of groundwater levels during plan implementation. Any such action should be in coordination with Tulare County, including the potential *for the continuation by the County of existing programs for drought mitigation assistance implemented during the last major drought.*

4. **WATER QUALITY - DISADVANTAGED COMMUNITIES (DACS)**
   a. **COMMENTORS:**
   Community Water Center
   b. **SUMMARY OF COMMENTS:**
   One commenter asserts that the GSP does not provide sufficient monitoring for water quality purposes, and does not establish sufficient measurable objectives and minimum thresholds related to groundwater quality that are specifically applicable to public drinking water systems and domestic water users. The commenter also asserted that the GSP does not provide sufficient protections against water quality problems that may be identified through existing or additional monitoring.
   c. **MASTER RESPONSE:**
   As a general proposition, the GSP recognizes the importance of protecting drinking water quality but also recognizes that water quality is already currently being addressed through a variety of programs and by numerous agencies with the authority and responsibility to specifically manage water quality. The GSA desires to coordinate with these agencies that have existing water quality regulations to avoid duplication of efforts and to utilize limited resources. To the extent the commenters suggest that greater water quality monitoring and protective actions should be provided for in the GSP, the GSA responds that such monitoring and protections, outside the context of existing water quality regulations and monitoring efforts, would be duplicative and outside the requirements that SGMA establishes for GSPs.

   Consistent with our agreements with existing identified DACs, the GSA has established broad water quality minimum thresholds and measurable objectives, utilizing existing water quality monitoring programs. As noted in the prior master comment response, the PUD/CSDs that are cooperating with the GSA in the development of this GSP had the opportunity to propose their own management area, with distinct minimum thresholds and measurable objectives, as the commenters have suggested. Specifically as noted in Section 1.4.3.2 of the GSP, the agreements with PUD/CSDs feature the following provisions:
   - PUD/CSDs have the opportunity to request a separate management area, with distinct minimum thresholds and measurable objectives to meet the sustainable management requirements. If they so elect, the PUD/CSDs will define the minimum thresholds and measurable objections that will apply within the PUD jurisdictional boundaries, in

conformance with state law.

- The PUD/CSDs agreed that if they do not elect to become a separate management area or if the proposed thresholds and objectives do not meet state legal requirements, then the GSA will prepare thresholds and measurable objectives needed to comply with state law and the PUD/CSDs will agree to implement them as necessary to meet the sustainable groundwater management requirements or until the PUD as a separate management area proposes thresholds and objectives that meet state requirements

None of the PUD/CSDs elected to propose a management area, nor have they proposed minimum thresholds or measurable objetives to be applied in their areas that are different or distinct from the remainder of the GSA planning area. The GSA will revisit this issue if and when the PUD/CSD representatives identify a need or desire for a separate management area, under the terms of the cooperative agreements. Staff will be recommending that these provisions be highlighted in the text of the GSP as a response to the comments received.

Regarding the comments suggesting that the GSA should be collecting data from the public water systems and individual domestic water users, the GSA has in fact been planning on collecting such data, and staff will recommend that additional text be added to the GSP to recognize this.

d. STAFF RECOMMENDATIONS

Recommendation 4.a. Staff recommends that the GSA governing board consider adding the following text to end of Section 3.5.1.3.1 (Measureable Objectives and Interim Milestones/Groundwater Quality/Process for Determining Measurable Obectives and Interim Milestones).

Under the terms of the cooperative agreements with the PUD/CSDs, those agencies have an ongoing opportunity propose minimum thresholds for additional constituents and determine whether additional changes to the monitoring network should be made to address water quality issues. The GSA will consider such proposals when made.

In addition, the GSA will seek to collect data from the public water systems as part of monitoring efforts. The collected data will reflect what these public water systems report to existing regulatory agencies to determine if existing regulatory requirements are being met and to determine if specific management actions would be warranted by the GSA under its authority to manage groundwater. The

GSA will be monitoring and coordinating these items to determine if groundwater pumping activities are contributing to undesirable effects related to degraded water quality.

5. **PUBLIC PARTICIPATION**
   a. **COMMENTORS:**
   Audubon California / Community Water Center / The Nature Conservancy (joint letter), Community Water Center (individual letter), Woodville Public Utility District
   b. **SUMMARY OF COMMENTS:**
   Commenters asserted that public comment was not sufficiently invited or that public noticing requirements were not met.
   c. **MASTER RESPONSE:**
   The GSA complied with all applicable statutory notice requirements in releasing the GSP. In addition, the GSA formed a Groundwater Planning Commission specifically for the purpose of expanding public participation. This step is not required by SGMA, and provides a higher degree of public participation than that provided by the majority of other GSAs.

   In addition, the GSP includes a detailed description of public meetings that were held in the planning process for the basin wide coordination agreement, which included all CSDs and PUDs in the current GSA service boundaries. As part of GSA formation, the irrigation district reached agreements with the CSD and PUD within its proposed boundaries to discuss rights and duties. The MOUs specified that the CSD and PUD could select their own representative to the Groundwater Planning Commission, the advisory board for the GSA. Notice of the Groundwater Planning Commission meetings and Irrigation District Board of Director meetings were sent to the CSDs and PUDs for distribution to their customers.

   All of the multitude meetings held over the past two years have been open to the public and conducted in a manner than encouraged public participation. Although many meetings may not have had a segmented portion of the meeting devoted to public comment, where no such segmented portion was provided, public comment was instead invited and encouraged throughout the entire meeting, and members of the public were never discouraged from offering comments. In fact, one of the commenters on this topic was a frequent public commenter during these unsegmented comment opportunities.

Staff will not be recommending any additional GSP text in response to these comments.

d. STAFF RECOMMENDATIONS

NA

6. <u>LAND USE (FUTURE GROWTH) – TULARE COUNTY/DACS</u>

a. COMMENTORS:

County of Tulare

b. SUMMARY OF COMMENTS:

The County of Tulare requested various clarifications regarding County and LAFCO authority over land use and growth issues related to or impacted by groundwater use and groundwater planning.

c. MASTER RESPONSE:

The comments received from the County of Tulare on the topic of land use and growth are clarifying in nature. Section 1.4.12.1 of the GSP adequately describes all of the updated plans. As land use in the identified communities is governed by Tulare County and is not directly addressed through the GSP, inclusion of a copy of these plans in the GSP is not necessary. Staff recommends clarifying language regarding individual domestic wells, consistent with changes recommended in response to other comments.

In addition, the GSA notes that the substantive land use and growth related issues involving public water systems and individual domestic water users will be addressed within the Groundwater Accounting System described in Section 5.2.1 of the GSP, and in the policies to be adopted in furtherance of that section, particularly policies related to accounting for municipal water agencies groundwater use and planning. See Master Responses 3 and 4 above.

d. STAFF RECOMMENDATIONS

Staff recommends adding the following text to the following GSP sections:

Recommendation 6.a. End of section 1.4.8.2 (GSA Plan Area/Communities Dependent Upon Groundwater/Groundwater Dependent Communities)

Groundwater dependent communities may also encompass individual domestic wells. Identification and monitoring of existing domestic water wells is difficult due to the lack of existing permitting and tracking information, and will be an item of future data development as part of GSP implementation.

7. **WATER BUDGETS/TECHNICAL ISSUES**

   a. **COMMENTORS:**
   Arvin-Edison Water Storage District/Shafter-Wasco Irrigation District (joint letter) Community Water Center (individual letter), County of Tulare, Hancock Farmland Services, Westchester Group Invesetment Management,

   b. **SUMMARY OF COMMENTS:**
   Commenters suggested or requested clarification and higher degree of specificity within the GSP regarding water budget conclusions, including sustainable yield determinations and landowner specific allocation methodologies.

   c. **MASTER RESPONSE:**
   Many of the details requested in these comments are provided in various analyses included in appendices, in particular the Tule Subbasin Coordination Agreement and the studies attached to that Agreement. Given the complexity of those attachments, the GSP itself was drafted in a manner to provide sufficient specificity while leaving the finer details to the appendices. Given that the information sought by the commenters can be found in the appendices, no changes to the GSP are recommended in response to these comments.

   To the extent the comments suggested that landowner-level allocation details be provided in the GSP, the GSA notes that these details are more appropriately determined in the specific policies to be adopted to implement the Groundwater Accounting System action item described in Section 5.2.1 of the GSP. These policies are presently in draft form, and are publicly available for review in advance of anticipated approval after January 2020. This action is sufficiently described in the GSP and no additional language is recommended by staff to address these comments.

   d. **STAFF RECOMMENDATIONS:**
   NA.

8. **GENERALIZED COMMENTS**

   a. **COMMENTORS:**
   Multiple

   b. **SUMMARY OF COMMENTS:**
   See attached Matrix

   c. **MASTER RESPONSE:**
   These comments are general in nature and as such are not susceptible to specific responses. These comments are noted in the attached matrix for informational purposes.

d. **STAFF RECOMMENDATIONS:**
NA.

9. **STAFF ADDITIONS/MODIFICATIONS**

9.1 - Clerical/Administrative/Non susbstantive

a. **Summary**

Various formatting, numbering, spelling, grammatical, organizational and other administrative corrections.

b. **Staff Recommendations**

Recommendation 9.a. 4 Creeks to provide

9.2 – No Authority or Intention to Affect Water Rights – Non-Waiver – Non-Admission

a. **Summary**

During development of the Coordination Agreeent, the collective GSAs within the Subbasin agreed to language for the Coordination Agreement to clarify that nothing in the water budgets, or the decisions as to how to calculate and divide the available Subbasin Sustainable Yield, should be construed as affecting any water rights of any landowner or any agency or entity that represents landowners (referred to in the Water Code, section 19, as a "Person"). Staff notes that this same intent should apply to the GSP, and to all conclusions and management actions called for under the GSP, and recommends that language similar to that included in the Coordination Agreement be added to the GSP.

b. **Staff Recommendations**

Recommendation 9.b. Add the following text to the end of section 1.3.3 (Introduction to GSP/Agency Information/Legal Authority):

It is noted that, consistent with § 10720.5(b) of SGMA, which provides that nothing in SGMA or in a plan adopted under SGMA determines or alters surface or groundwater rights under common law or any provision of law that determines or grants surface water rights, nothing in this Coordination Agreement is intended to modify the water rights of any Person (as that term is defined under Section 19 of the Water Code) . The GSA notes that it does not have the authority to modify any water rights through adoption of this GSP, nor does it intend that any in this GSP be construed as an admission by any Person (including without limitation the GSA, the Irrigation District or by any landowner or user of groundwater) regarding any subject matter of this GSP, including without limitation any water right or priority of any water right that is claimed by any Person. Nor shall this GSP in any way be construed to represent an admission by a Person with respect to the subject or sufficiency of another Person's claim to any water or water right or priority or defenses thereto, or to establish a standard for the purposes of the determining the respective liability of *any Person, except to the extent otherwise specified by law. Nothing in this GSP shall be construed as a waiver by any Person of its election to at any time assert a legal claim or argument as to water, water right or any subject matter of this GSP or defenses thereto. The division of Sustainable Yield among the GSA landowners under any Management Action adopted by this GSP does not constitute any determination that groundwater extractions by a landowner in excess of a budgeted amount would necessarily cause an undesirable result or that extractions less than a budgeted amount would necessarily not cause an undesirable result.*

The GSA intends, to the fullest extent permitted by law, to preserve the water rights of all Persons affected by this GSP as they may exist as of the adoption date of the GSP or at any time thereafter. The GSA further intends that any dispute or claim arising out of or in any way related to a water right alleged by a Person shall be separately resolved before an appropriate judicial, administrative or enforcement body with proper jurisdiction.

9.3 – Clarification of Per Acre Division of GSA Sustainable Yield

a. Summary

The GSP is based on the assumption that the Subbasin Sustainable Yield will be divided at both the Subbasin level (as amongst the GSAs) and the GSA level (as amongst landowners) on a per-acre basis. Though comments were received during the public review period on this top, through the public outreach process, it has been asserted that a more detailed and landowner-specific process, which includes assessment of individualized historic use data, needs to be completed in order to allocate available Sustainable Yield in a manner that is consistent with groundwater rights. The GSP does not make a determination of the validity of these assertions. Instead, the calculation of Sustainable Yield for the GSA's portion of the Tule Subbasin under this GSP has been developed with the understanding that the determinations being made are for purposes of meeting SGMA requirements, and expressly not for the purpose of determining relative groundwater rights of landowners. In particular, the Groundwater Accounting System, as described in section 5.2.1, is not intended to constitute a determination of water rights. This understanding is consistent with § 10720.5(b) of SGMA, which provides that nothing in SGMA or in a plan adopted under SGMA determines or alters surface or groundwater rights under common law. Any determination to divide the Sustainable Yield in any particular manner should not be deemed to conclusively determine the water rights of landowners.

Moreover, the GSA, like the other GSAs within the Tule Subbasin, consider that the per acrea basis of dividing GSA specific Sustainable Yield quantities represents the most readily-available and implementable manner of honoring correlative groundwater rights, because it is based on the well-documented conclusion that beneficial uses of the lands of the Tule Subbasin are, for the most part, uniformly agricultural in nature, and uniform in intensity of agricultural use. Furthermore, any individualized assessment that is based on historic use, even if it would be legally desirable or required in a legal process such as an adjudication, is not capable of being used due to the current state of data keeping for the thousands of individual landowners that exist within the entire Tule Subbasin. A decision to use historic use as at least one factor, therefore, would delay indefinitely the adoption any meaningful management plan under SGMA.

For these reasons, the per-acre division has been used for the purpose of the Groundwater Accounting System management action. At the same time, with the collection of additional data, refinements to the allocation or division methodologies will be considered in potential future updates, to and including the potential use of historic pumping data if such data is both available and is agreed to be used as the basis for any further refinement of allocation methodologies.

In order to clarify this issue and to acknowledge the potential future availability of alternative allocation or division methods, staff recommends adding language to the general description section for Management Action 5.2.1 (Agency Groundwater Accounting Action).

b. Staff Recommendations

Recommendation 9.c. Add the following to the end of Section 5.2.1 (Management Actions/Agency Groundwater Accounting Action/General Description):

As noted above, for purposes of creating a water budget pursuant to 23 Cal. Code Regs. §354.18, the GSAs in the Tule Subbasin have agreed that, for water budget accounting purposes, the Sustainable Yield for the Subbasin shall be divided amongst the GSAs for purposes of development of their GSPs as described in the attached water budget. The basin-wide portion of the Sustainable Yield identified in the water budget was divided amongst each GSA by multiplying that GSA's proportionate areal coverage of the Tule Subbasin times the total Subbasin Sustainable Yield.

In a similar manner, this Management Action (the creation of a Groundwater Accounting System) is intended to implement a division of the sustainable yield amongst affected landowners on the basis of a landowner's proportionate areal coverage of the GSA area times that portion of the Subbasin Sustainable Yield assigned to the GSA under the Coordination Agreement. This method of division of the GSA's portion of Subbasin Sustainable yield is consistent with Irrigation District law related to District water supplies in general.

The water budget to be divided amongst the GSA landowners under this Management Action is not an allocation or final determination of any water rights (including claimed appropriative or prescriptive rights). This understanding is consistent with § 10720.5(b) of SGMA, which provides that nothing in SGMA or in a plan adopted under SGMA determines or alters surface or groundwater rights under common law or any provision of law that determines or grants surface water rights. Rather, the use of the proportional acreage basis for dividing up the water budget for accounting purposes, will be used because it represents the most readily-available and implementable manner of accounting for the water budget for GSP purposes at this time, without the need for determining specific water rights, which would be controversial and time consuming and could not be completed in the time frames applicable to GSP development.

Similar to the Subbasin, the GSA will be collecting additional data and will consider refining or changing the method of dividing Sustainable Yield for internal GSA water budget purposes in future updates, including the potential use of historic pumping data if such data is both available and is agreed to be used as the basis for division.

9.4 – Clarification of Treatment of Imported Recharged Water

a. Summary

In informal discussions amongst GSAs in the Subbasin, some parties suggested that the GSPs should uniformly specify that any imported water that is used in groundwater recharge or banking projects, or for direct groundwater replenishment, should maintain its status as imported water, and therefore fully accounted for as an asset of the importing entity. The GSA agrees with this concept, and staff suggests wording be added to the GSP to clarify this.

b. Staff Recommendation

Recommendation 9.d. Add the following text to the end of Section 2.4.2.6 (Tule Basin Setting/Water Budget/Groundwater Budget/Sustainable Yield):

It should be noted that the GSAs have agreed, and this GSP assumes, that the exclusion of water imported by an entity from the calculation of Sustainable Yield of the Subbasin applies to imported water that is used for groundwater recharge or water banking purposes. The recharged or banked imported water retains its characterization as imported water even after it is used for recharge or banking purposes, and therefore is accounted for as being for the benefit of the importing entity, and not an addition to Sustainable Yield.

Re: McMullin Area Groundwater Sustainability Plan (GSP), Kings Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the McMullin Area Groundwater Sustainability Agency's (GSA's) McMullin Area Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results and minimum thresholds were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of potential ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as only 1 out of 54 of our comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

TNC recommendation: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were excluded based on lack of continuous saturation between surface water and groundwater. This justification of automatic removal is incorrect and inconsistent with the definition of ISWs. The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. Therefore, potential ISWs are not being managed in the GSP.

Map and Assessment of potential ISWs:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the McMullin Area GSP, 5.5 river miles have an uncertain connection to groundwater. Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on surface water-groundwater interconnectivity and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 740 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not to adequately identify, map and consider GDEs. We believe that this does not meet plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on groundwater levels that were greater than 30-ft at a single point in time. This is a technically incorrect approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30-ft or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and may result in the omission of ecosystems that are groundwater dependent.

TNC recommendation: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in Attachment D which provides best practices for using the NC dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). The GSP only focused on a subset of water use sectors, including urban and agricultural users of groundwater. This is problematic because key environmental uses of groundwater are not being accounted for as water supply decisions are made using this budget nor will they likely be considered in project and management actions.

[1] *Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf*

TNC recommendation: As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Potential GDEs are located along surface water bodies where no shallow groundwater monitoring is proposed. Potential ISWs have been dismissed in the GSP, without proposed recommendations to improve ISW identification, mapping, and estimates of depletions. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the McMullin Area Groundwater Sustainability Plan

The McMullin Area Groundwater Sustainability Plan (GSP) adopted November 6, 2019 was reviewed by TNC. Public draft GSP comments and responses, provided as Appendix 2C of the GSP, were reviewed and are referred to below. The TNC comments and responses are also provided in Attachment F of this letter. This attachment lists our original comments on the complete public draft GSP as submitted to the GSA during the public comment period, and states whether or not they were addressed in the final GSP [as green text within brackets]. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 2.5.1 Description of Beneficial Uses and Users (p. 2-37)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* There are state-owned lands in the McMullin Area, the Alkali Sink Ecological Reserve and the Kerman Ecological Reserve, both owned and managed by CDFW. CDFW was invited to participate in the McMullin GSP as an Interested Party, but no other groups were listed as environmental users of groundwater. **Please identify whether or not the following beneficial uses and users of groundwater in the Subbasin are present: Protected Lands, including refuges, conservation areas, and recreational areas; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
- *[Our comment was not identified in the response to comments. No changes to the GSP text were made.]* The types and locations of environmental uses, species and habitats supported, instream flow requirements, and other designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. **To identify environmental users, please refer to the following:**
  - The NC Dataset (https://gis.water.ca.gov/app/NCDatasetViewer/) which identifies potential presence of groundwater dependent ecosystems in this basin
  - The list of freshwater species located in the Kings Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.
  - CDFW's California Natural Diversity Database (CNDDB) - https://www.wildlife.ca.gov/Data/CNDDB
  - USFWS's IPAC report for the McMullin Area - https://ecos.fws.gov/ipac/

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8).

[Section 2.2.1 Monitoring and Management Programs - Surface Water Monitoring (p. 2-20)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section briefly describes the types of monitoring performed by the Kings River Water Authority (KRWA), the Friant Water Authority (FWA) and the San Luis Delta-Mendota Water Authority (SLDMWA), and the ditch companies. There is no mention of ISWs or GDEs or how they are monitored. **Please explain the relationship of existing stream flow monitoring to the protection of ISWs and GDEs, and if there are instream flow criteria for the ISWs.**

[Section 2.2.2.4 San Joaquin River Restoration Program (p. 2-26 to 2-27)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The San Joaquin River Restoration Program (SJRRP) requires the release of flows from Friant Dam to the confluence with the Merced River to support the life-stages of salmon and other fish species. These restoration flows will allow more groundwater seepage when the system is fully operational, estimated to be after 2029. This section should discuss or reference any instream flow requirements, especially flow needs for critical species, including the amount, time of year when the flow minimum is specified, the duration, the species for which it applies, associated permits that set forth the requirements, and the regulating agency setting forth the compliance requirements. **Please discuss the potential impact of the SJRRP on the wetlands and potential GDEs present along or adjacent to the river.**

[Section 2.3 Relation to General Plans (p. 2-28 to 2-29)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The Fresno County General Plan was adopted prior to the development of the GSA. This section should be modified to include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin, and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**

[Section 2.3.4 Permitting New or Replacement Wells (p. 2-29 to 2-30)]

---

[2] *Available online at:* *https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/*

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please include a discussion of how future well permitting will be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF vs. SWRCB and Siskiyou County, No. C083239). **Compliance of well permitting programs with this requirement should be stated in the GSP.**

<u>Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)</u>

[Section 3.1.7 Cross-sections (p. 3-15)]

- *[The GSA's response does not address our comment. Minor changes to the GSP text do not address our comment.]* The basinwide cross sections provided in Figures 3-9 through 3-14 (pp. 3-16 through 3-21) are regional, and do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. The cross-sections have been taken from a 1969 source and, as reproduced in the GSP, are very difficult to read and understand. **Please reproduce the regional cross-sections so that they can be understood by the reader and update them to illustrate data obtained from more recent well installations. Include an example near-surface cross sections that depicts the conceptual understanding of shallow groundwater and river interactions at different locations, as well as any potential GDEs and ISWs**.

[Section 3.1.8.1 Geologic Formation (pp. 3-22 to 3-25)]

- *[The GSA's response states: "The wells in MAGSA's monitoring network are only in the unconfined zone." This response addresses our comment, however no GSP text changes were made.]* There are two water-bearing formations, the younger alluvium and the deeper, older alluvium. In the western part of the Subbasin, they are divided by three clay layers, A, C and E clays; the E-clay is commonly known as the Corcoran Clay. Confined conditions exist below the Corcoran Clay. The document states that "At the time of writing this HCM, insufficient data was available to verify if confined groundwater conditions exist between the C-Clay and E-Clay within the MAGSA; however, based on the available data from nearby areas, it is assumed that confined conditions exist between the two in the MAGSA. This is still being investigated by the Kings Basin Coordination Efforts" (pp. 3-25). The extent of the clay layers is shown in Figure 3-17 (p. 3-26). **It is important to determine if confined conditions exist between the C-Clay and the E-Clay, and to confirm that only wells with screened intervals in the unconfined aquifer are being used to compare with surface water to identify and confirm potential GDEs.**

[Section 3.1.8.1 Aquifer Characteristics and Properties (p. 3-27)]

- *[The figures labels have been corrected. The GSA's response does not address the rest of our comment and no changes to the GSP text were made.]* In the McMullin Area, the base of the usable aquifer corresponds with the base of fresh water, generally defined as groundwater with total dissolved solids (TDS) of 2,000 milligrams per liter (mg/l) (KDSA, 2010). Figure 3-17 (p. 3-28) shows the base of the aquifer defined this way but is mislabeled as Figure 3-13. **Please correct figure labels for Figures 3-17, 3-18, and 3-19 (labeled as 3-13, 3-14 and 3-15).** As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.

[Section 3.1.12 Recharge and Discharge Areas (p. 3-40 to 3-41]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Wetlands were mapped along the San Joaquin River, as identified from US Forest Service's National Wetland Inventory, according to the GSP. Two other areas are mentioned, the 1,800-acre Kerman Ecological Reserve and the 930-acre Alkali Sink, both consisting of grassland habitat with seasonal vernal pools. **Please discuss in the GSP that portions of these Reserves are considered potential GDEs and refer to Figure 3-75. Also, if the Wetland Inventory was in fact the US Fish and Wildlife Service (USFWS) National Wetlands Inventory (NWI), then correct the text and reevaluate the data. The NWI does not always include or segregate separate existing wetlands that are on the periphery of other features. Please describe the wetland types in more detail. If they are truly vernal pools confined by a clay layer then they are not GDEs, but they must meet the criteria of a vernal pool as described by the California Rapid Assessment Methodology or the United States Army Corps of Engineers to qualify.**

Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)

[Section 3.2.7 Surface Water and Groundwater Interconnection (p. 3-108 to 3-114)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please provide depth to groundwater contour maps. See Attachment D for best practices for completing this step. Specifically, ensure that the first step is contouring groundwater elevations, and the subtracting this layer from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape**. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make.

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. The text states that "It has been adequately determined that there is no evidence as to the presence of continuous interconnected surface water groundwater systems within the MAGSA along the San Joaquin River therefore this criterion is not applicable to the MAGSA" (p. 3-108). TNC disagrees with the conclusion that the interconnection must be continuous in time for surface water to be considered interconnected. In fact, the text state that "When river discharge is high, the groundwater elevations in wells MW-09-36 and MW-09-37 are higher than the channel bed elevation" (p. 3-110). No data were included to show the relationship between the depth to groundwater and the riverbed. **Please provide a cross-section and/or corresponding hydrographs to show the relationship between the river channel and the depth to groundwater at wells near the river.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface Digital Elevation Model that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. Groundwater elevations that are always deeper than 50 feet below the land surface can be used to identify the aboveground reaches as disconnected surface waters. The data presented in Figure 3-71 (p. 3-110) indicate that the depth to groundwater in monitoring well MW-09-39 was within 25 feet of the ground surface from October 2009 through January 2017, and within 5 feet in April 2011 and on several occasions since January 2017. The data clearly show that at times the surface water and groundwater are interconnected. **Please evaluate with depth to groundwater contour maps as described above, and see Attachment D for best practices for completing this step.** TNC disagrees with the text on p. 3-113 stating "Interconnected surface water sustainable management criteria do not apply within the MAGSA reaches of the San Joaquin River…". Without further documented evidence, ISWs must be retained for the consideration of sustainable management criteria. **Please remove or restate this sentence. Expand the discussion of ISWs to include the above referenced recommendations on identifying and mapping ISWs and provide discussion of the depletions on specific rivers. Please reconcile any data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features in the Monitoring Network section of the GSP to improve ISW mapping.**

[Section 5.7 Depletion of Interconnected Surface Water (p. 5-42)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The document states that this criterion is not applicable to the MAGSA because the flow in the San Joaquin River is dry "at various times of the calendar year" (p. 5-42) below the Bifurcation Structure (Figure 5-10). There is no discussion of how the flow regime will change as part of the SJRRP. **Please provide a discussion of the expected effect of the SJRRP on flows, GDEs and ISWs along the San Joaquin River.**

<u>Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)</u>

[Section 3.2.8 Groundwater Dependent Ecosystems (p. 3-114)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The NC dataset is a starting point for GSAs to identify GDEs in their basin. The NC dataset comprises 740 acres of potential GDEs for the McMullin Area. The text states that rejected GDEs are depicted in purple in Figures 3-75 and 3-76, however this is not the case. **Please map the original NC dataset, and clearly document which polygons were added (and what local sources were used to identify them), removed (and the removal reason), and kept (from the original NC dataset)**. The basin's GDE shapefile, which is submitted via the SGMA Portal, should also include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were added or removed).
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The text states on p. 3-114: "As seen in Figure 3-75 and Figure 3-76, groundwater elevations can be extremely low throughout MAGSA, indicating a lack of groundwater dependent ecosystems (GDEs)," however these figures do not show groundwater elevations or depth to groundwater. **Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network**. Specifically, please note:
    - *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please provide depth to groundwater contour maps as described above as related to Checklist Items 8, 9 and 10 for Section 3.2.7**
    - *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The text states (p. 3-114): "Recognizing that much of the Kings Subbasin has a depth to groundwater greater than the deepest vegetative GDE rooting depth of thirty feet, many of the GDEs identified in the NC Dataset Viewer were mischaracterized." In TNC's GDE Guidance, the depth criterion of 30 feet is presented as a criterion for *inclusion*, not a standalone criterion for *exclusion*. In other words, if groundwater is within 30

feet of the ground surface, then a GDE can be identified. If it is not, then further analysis must be conducted (see Appendix III of the GDE Guidance, Worksheet 1, for other indicators of GDEs). In addition, many phreatophytes can and will root deeper than 30 feet, but are commonly constrained by the saturated zone at and below the ground water table. As groundwater declines or rises, roots redistribute over the water table in the unsaturated zone. This may happen on a seasonal and annual basis. **Please remove the 30-foot criteria for excluding GDEs and present a more comprehensive analysis for identifying GDEs in the Subbasin, as outlined in Appendix III (Worksheet 1) of the GDE Guidance.**

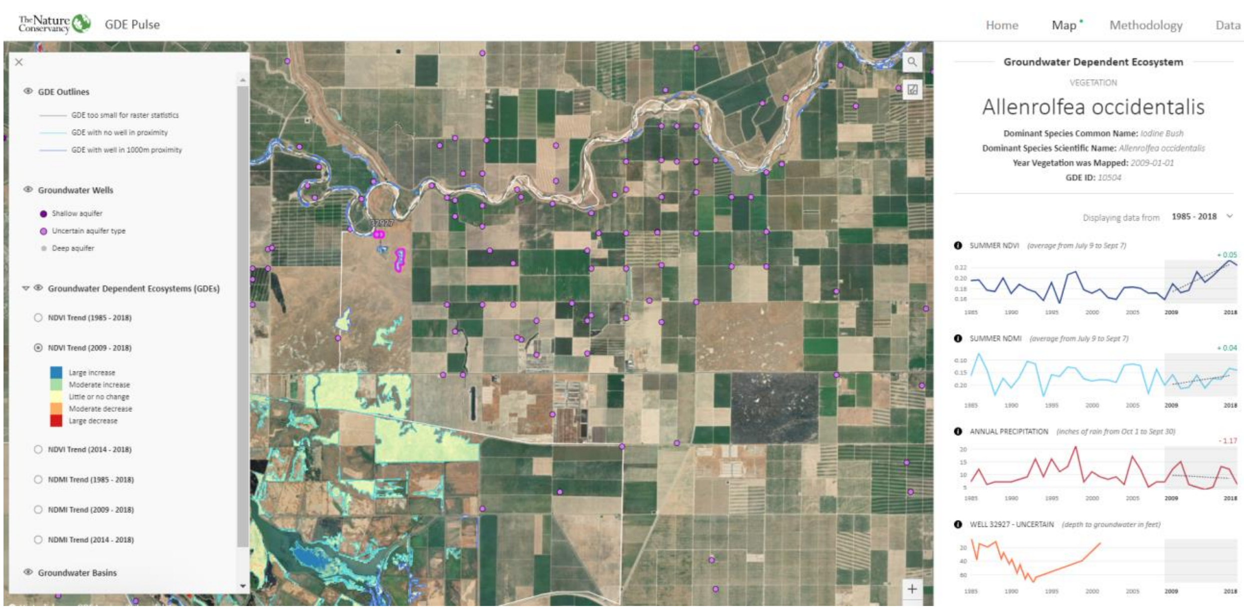
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The actual rooting depth of vegetation growing in the area should be considered. Furthermore, rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant, as mentioned above. Maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not prefer to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths. **Please indicate what vegetation is present in the possible GDEs.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The Spring 2017 groundwater contours were used to exclude any GDE where the depth to groundwater was deeper than 30 feet. It is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2017) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Ensure that groundwater condition data prior to the SGMA benchmark date of January 1, 2015 is included in the analysis. Please refer to our comment above related to Checklist Items 8-10 for Section 3.2.7, and to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network**.
- *[One sentence added to GSP text: "This 100-ft buffer is based on a California Department of Transportation typical wetland setback (CDOT, 2019)." However, this addition to the text does not address our comment, nor does this buffer rule describe whether groundwater conditions in the basin are supporting GDEs.]* The text states on page 3-116: "The Kings Subbasin also categorized GDEs within 100 feet of the Kings River and the San Joaquin

River as "Possible GDEs." **Please clarify how the 100-foot buffer was used to include or exclude GDEs in the McMullin Area, and how this is supported by groundwater level and plant physiological data. If there is a potential GDE near the river, we suggest the entire GDE is included, rather than using an arbitrary 100-foot cutoff.**

<u>Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)</u>

[Section 3.2.8 Groundwater Dependent Ecosystems (p. 3-114)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Once potential GDEs are identified, please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present**. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the McMullin Area:



- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please provide an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes the vegetation types or habitat types and rank the GDEs as having a high, moderate or low value; and what characterizes the rank.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were**

found in or near any of the GDEs since some organisms rely on uplands and wetlands during different stages of their lifecycle. Resources for this include the list of freshwater species located in the Kings Subbasin can be found in Attachment C of this letter, the Critical Species Lookbook, and CDFW's CNDDB database.

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **For each identifiable GDE unit with supporting hydrological datasets please include the following:**
  - Plot and provide hydrological datasets for each GDE.
  - Define the baseline period in the hydrologic data.
  - Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater.
  - Explore cause-and-effect relationships between groundwater changes and GDEs.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **For each identifiable GDE unit without supporting hydrological datasets please describe data gaps and/or insufficiencies.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Compile and synthesize biological data for each GDE unit by including:**
  - Plots of biological datasets for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.
  - Describe data gaps/insufficiencies.
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* **Description of potential effects on GDEs, land uses, and property interests, including:**
  - Cause-and-effect relationships between GDE and groundwater conditions.
  - Impacts to GDEs that are considered to be "significant and unreasonable".
  - Report known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities.
  - Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).
  - Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 3.3.8 Historical Water Budget (p. 3-131)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The text states that groundwater pumping and the lack of surface water in the McMullin Area has induced large groundwater flows into the McMullin Area. This inflow has been included in the historical budget, but it is not included in future budgets. **Please quantify the estimated amount of induced groundwater flow in the historical budget, clearly indicate if this amount is included in the**

current budget, and why there are differences in inclusion from historical, current and future budgets.

- *[The GSA's response states: "The only riparian and wetland areas are located along the southern side of the San Joaquin River. These cover relatively minor areas, and the evapotranspiration were estimated as part of the total evaporation from the San Joaquin River, which was estimated internally as part of the River seepage estimates. Native vegetation evapotranspiration would be from local rainfall and is captured in the Water Budget variable 'Rainfall Evaporation and Runoff.'" Please include a term for native or riparian vegetation and wetlands evapotranspiration in the McMullin Area historical, current, and future water budgets.]* **Please clarify whether a term is included for native or riparian vegetation evapotranspiration and for wetlands in the McMullin Area historical, current, and future water budgets.**

<u>Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)</u>

[Section 4.1 Sustainability Goal (p. 4-2)] The Sustainability Goal does not consider GDEs or ISWs.

- *[The GSA's response does not address our comment. Minor changes to the GSP text do not address our comment.]* **Since GDEs are likely present in the Subbasin (see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included.**
- *[The GSA's response does not address our comment. Minor changes to the GSP text do not address our comment.]* The Plan states that there are time periods of ISW connectivity along the San Joaquin River; however, they are dismissed because they are not continuously connected. **TNC notes evidence of connectivity between surface water and groundwater and potential GDEs have been identified near the San Joaquin River. We disagree with the statement that there are not ISWs within the GSA. Even though the ISWs are not continuously connected (see comments under Checklist Items 8-10) they should be included in the Sustainability Goal.**
- *[The GSA's response does not address our comment. Minor changes to the GSP text do not address our comment.]* GDEs are dependent, in part, on suitable water quality; however, the Plan only considers water quality for irrigation and domestic use. **TNC recommends including ISWs and their potential GDEs in the sustainability goal and criteria. Since GDEs may be affected by water quality, they should be included in the Sustainability Goal.**

[Section 4.2 Groundwater Levels (p. 4-3)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Figure 4-1 (p. 4-4) represents Path A as shown in the DWR Sustainable Management Criteria BMP (Figure 15, Potential Paths to Sustainability). This is a problematic concept to implement since this Subbasin is already designated as being critically overdrafted, despite that the McMullin Area is not yet experiencing undesirable results. This approach may slow recovery of adjacent areas or have unintended consequences that contribute to undesirable results within the McMullin Area and adjacent areas. Please elaborate on how this continued groundwater decline will affect the ability of adjacent GSP areas within the Subbasin to recover, and how potential unintended consequences within the McMullin Area and adjacent areas will be evaluated.

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Sections 4.2.3 Measurable Objectives for Groundwater Levels (p. 4-10)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This Measurable Objective does not consider GDEs. **Please include GDEs (see comments under Checklist Items 8-10) in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.3 Measurable Objectives for Water Quality (p. 4-27)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This Measurable Objective does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Section 4.7 Interconnected Groundwater Surface Water Systems (p. 4-42)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The Measurable Objectives do not consider ISWs. The Plan states that there are time periods of ISWs along the San Joaquin River; however, they are dismissed because they are not continuously connected. Even though the ISWs are not continuously connected they should be included in the Measurable Objectives because they are still connected. **Please include ISWs (see comments under checklist items 16-20) in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial users of surface water that could be affected by groundwater withdrawals, including environmental. The SJRRP identifies instream flow needs for salmon in Reach 2a which forms the northern border in the Plan area (http://www.restoresjr.net/about/overview-map/). **Please include instream flow requirements in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28)

[Sections 4.2.2 Minimum Thresholds for Groundwater Levels (p. 4-6)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This Minimum Threshold does not consider GDEs. **Please include GDEs in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.2 Minimum Thresholds for Water Quality (p. 4-23)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This Minimum Threshold does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Section 4.7 Interconnected Groundwater Surface Water Systems (p. 4-42)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The Minimum Thresholds do not consider GDEs. GDEs are often adjacent to streams or associated with riparian corridors where ISWs exist, even if only seasonally or are discontinuous along a longitudinal profile. ISWs that are not continuously connected spatially and/or temporally are still ISWs and should not be excluded from this GSP. **Please include GDEs and ISWs in this section and whether the minimum thresholds will help achieve the sustainability goal as it pertains to the environment.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial users of surface water that could be affected by groundwater withdrawals, including environmental users. Instream flow requirements for salmon are identified in the SJRRP for a region that forms the northern border in the Plan area (http://www.restoresjr.net/about/overview-map/). **Please include instream flow and critical habitat requirements in this section and whether the minimum thresholds will help achieve the sustainability goal as it pertains to the environment.**

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 4.2.1 Undesirable Results (for Groundwater Levels) (p. 4-3)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses that could be adversely affected by chronic groundwater level decline. **Please add "potential**

adverse impacts to GDEs" to the list of potential undesirable results presented in Section 4.

- *[No response required.]* The GDE Pulse web application developed by TNC provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within and near the GSA. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture along the San Joaquin River. An example screen shot from the GDE Pulse tool is presented under Checklist Items 11-15 above.

[Section 4.5.1 Undesirable Results (for groundwater quality) (p. 4-20)]

- *[The GSA's response does not address our comment. Minor changes to the GSP text do not address our comment.]* This section only describes undesirable results in terms of meeting drinking water standards. The following is a link to a paper by Smith, Knight and Fendorf (2018) titled "Overpumping leads to California groundwater arsenic threat": (https://www.nature.com/articles/s41467-018-04475-3). **The section should be modified to state that overpumping and dewatering of aquitards has been identified as a potential source of elevated arsenic concentrations above drinking water standards in San Joaquin Valley aquifers. In addition, any potential undesirable results from degradation of water quality that may impact GDEs and freshwater species in the area should be discussed in this section.**

[Section 4.7 Interconnected Groundwater Surface Water Systems (p. 4-42)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section does not consider Undesirable Results for Interconnected Groundwater Surface Water Systems]. The Plan states that there are time periods of ISWs along the San Joaquin River; however, they are dismissed because they are not continuously connected. **Even though the ISWs are not continuously connected they should be included in the Undesirable Results. The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial users of surface water that could be affected by groundwater withdrawals, including environmental. The SJRRP identifies instream flow needs for salmon in Reach 2a which forms the northern border in the Plan area (http://www.restoresjr.net/about/overview-map/). Please include instream flow requirements and critical habitat designations in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

[Section 5.2 Groundwater Levels (pp. 5-3 to 5-16)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The text states that the unconfined, semi-confined and confined aquifers will be monitored separately. The proposed wells to be used for monitoring groundwater levels are shown in Figure 5-3 (p. 5-9). Many of the monitoring wells are missing well construction information, which is acknowledged as a data gap on p. 5-14. It is not clear exactly which aquifer is being monitored using the proposed system of 152 wells. **To accurately characterize GDEs, please clarify how the unconfined aquifer will be monitored and how many wells will be used.**

[Section 5.7 Depletion of Interconnected Surface Water (pp. 5-42 to 5-49)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* The text states several times that because the MAGSA is not setting criteria for ISWs, further expansion of the monitoring network or addressing data gaps is not deemed applicable at this time. However, because the identification and mapping of ISWs in Section 3.2.7 of the GSP was not adequate (see our comments on this section above), data gaps must be recognized, and a monitoring plan put in place to reconcile these data gaps prior to dismissal of these sensitive habitats. **Please reconcile these data gaps with specific recommendations (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features to improve ISW mapping and inform an adequate analysis.**
- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater <u>*and related surface conditions*</u> (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of complicated factors, and this relationship is not characterized or discussed. As such, it is not possible to determine whether the proposed monitoring is sufficiently protective to ensure significant and unreasonable impacts to GDEs and ISWs will be prevented. **To clarify if GDEs are present, consider adding monitoring of potential GDEs at any locations where ISWs have been present regardless of their seasonal or discontinuous nature.**

<u>Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)</u>

[Section 6.1 Introduction (p. 6-1) and 6.2.14 Project Ranking (p. 6-90)]

- *[Our comment was adequately addressed through GSP text changes. Thank you for including environmental benefits and multiple benefits as criteria for assessing project priorities.]* The Subbasin area includes many GDEs and ISWs (see our comments under checklist items 8-10 and 16-20 above) that are beneficial uses and users of groundwater, and may include potentially sensitive resources and protected lands. Environmental resource protection needs should be considered in establishing project priorities. In addition, consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**

[Section 6.2 Projects (pp. 6-5 to 6-93)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section identifies many important projects; however, the descriptions of Measurable Objectives for these projects only identifies benefits to water level and storage. **Because maintenance or recovery of groundwater levels or construction of recharge facilities may have potential environmental benefits, in many cases it would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.**
    - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
    - If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting ISWs.**
    - Recharge ponds, reservoirs and facilities for managed stormwater recharge can be designed to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such facilities have been incorporated into local Habitat Conservation Plans (HCPs) and Natural Community Conservation Plans (NCCPs), more fully recognizing the value of the habitat that they provide and the species they support. For projects that construct recharge ponds, **please consider identifying if there is habitat value incorporated into the design and how the recharge ponds will be managed to benefit environmental users.**
    - For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

[Section 6.3 Management Actions (p. 6-94)]

- *[The GSA's response does not address our comment and no changes to the GSP text were made.]* This section discusses the Management Actions for GSP implementation and SGMA compliance; however, these actions are focused on meeting groundwater level and storage measures and do not include support for GDEs or ISWs. **Please consider modifying the Management Actions to include education and outreach for protection of GDEs and ISWs. Please update Section 6.3.1.2 (p. 6-97) to include GDEs and ISWs.**

Attachment C

Freshwater Species Located in the Kings Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Kings Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[4] as well as on TNC's science website[5].

Scientific Name	Common Name	Legally Protected Species		
		Federal	State	Other
Birds				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	BCC	SCC	BSSC - First priority
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anas strepera	Gadwall			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron			
Aythya affinis	Lesser Scaup			
Aythya americana	Redhead		SCC	BSSC - Third priority
Aythya collaris	Ring-necked Duck			
Aythya marila	Greater Scaup			
Aythya valisineria	Canvasback		SCC

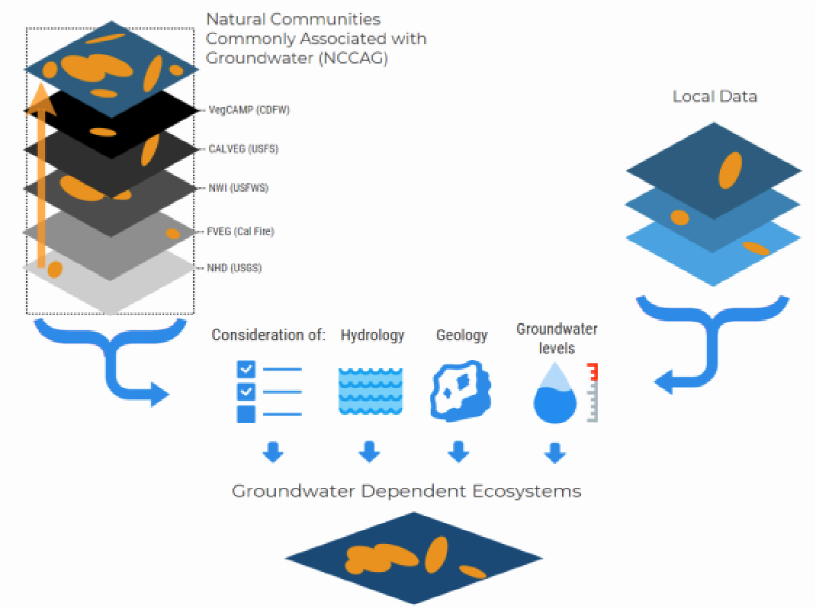
IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[6] *NC Dataset Online Viewer:* *https://gis.water.ca.gov/app/NCDatasetViewer/*

[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

[10] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

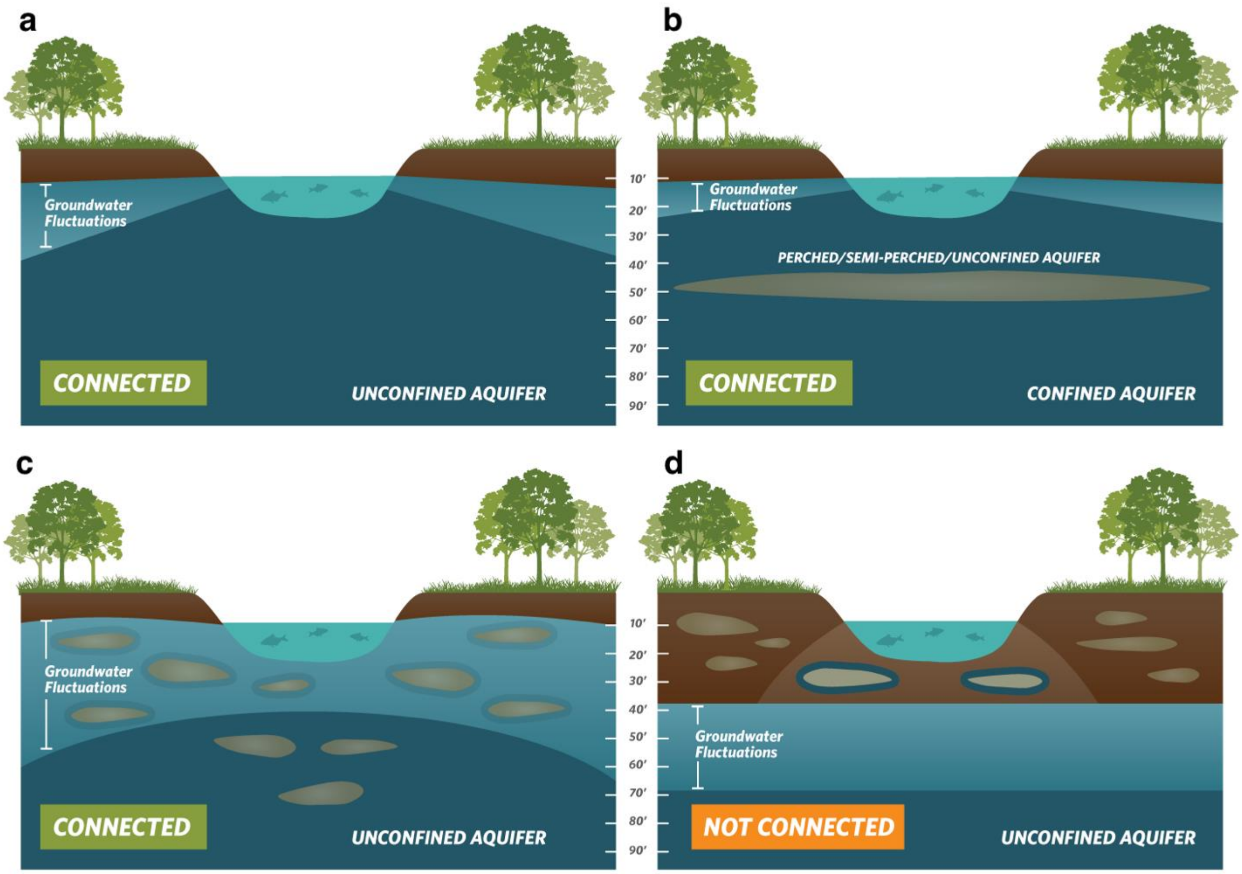

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

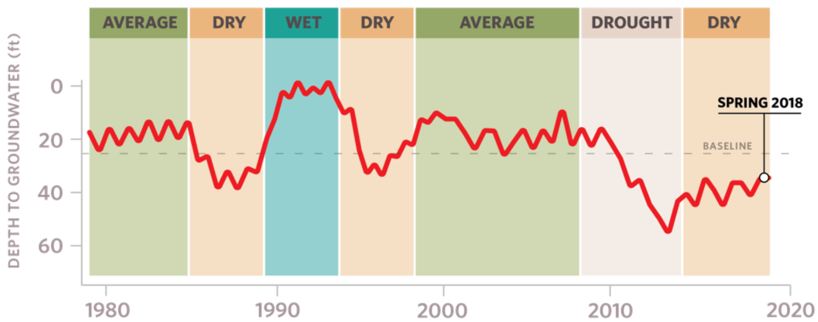

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

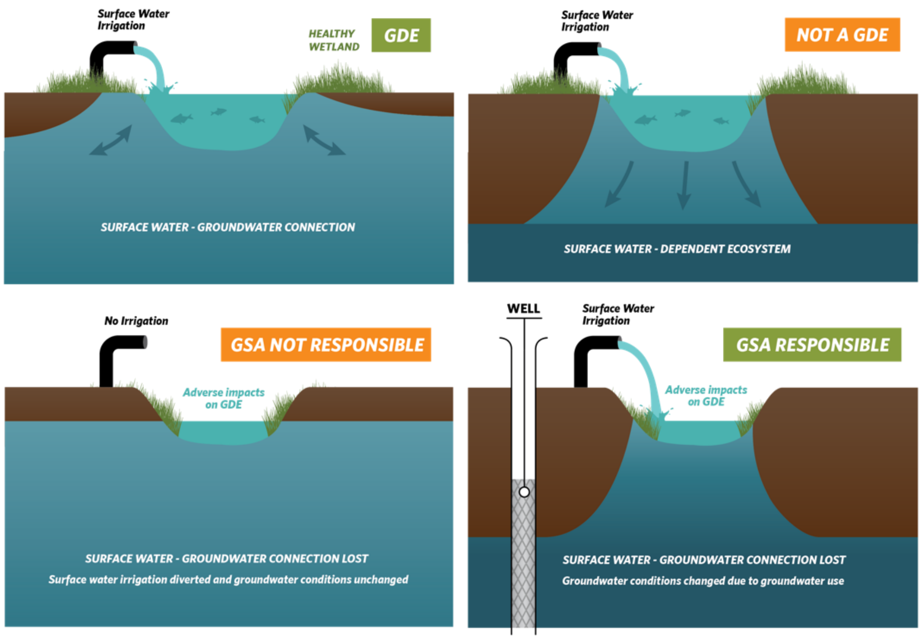

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

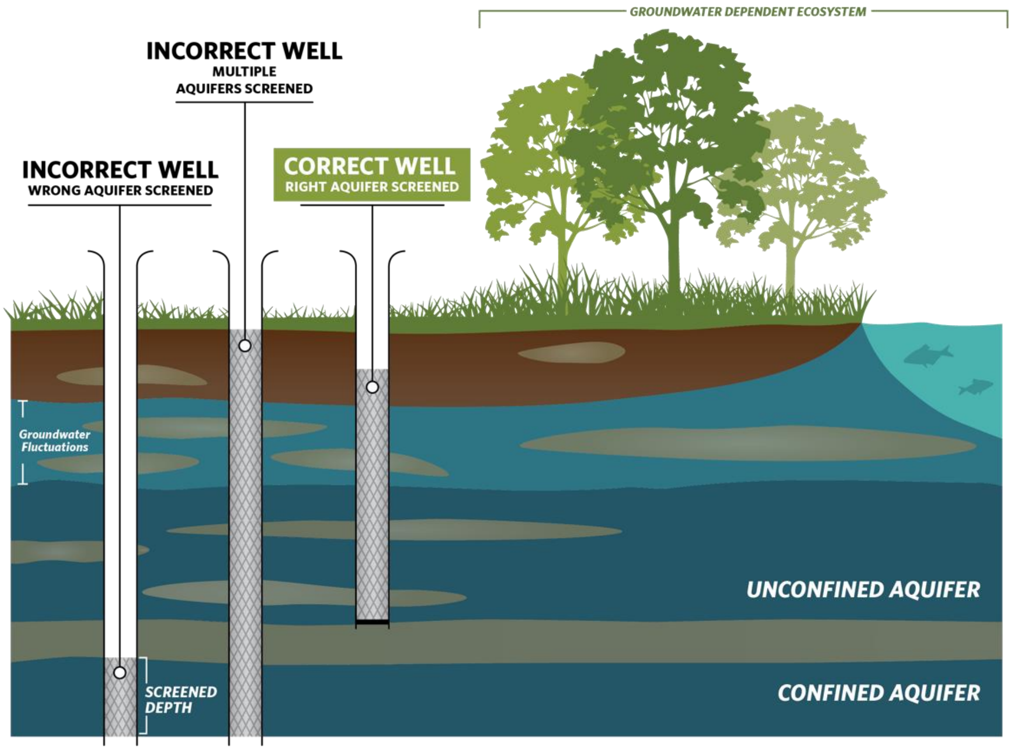

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

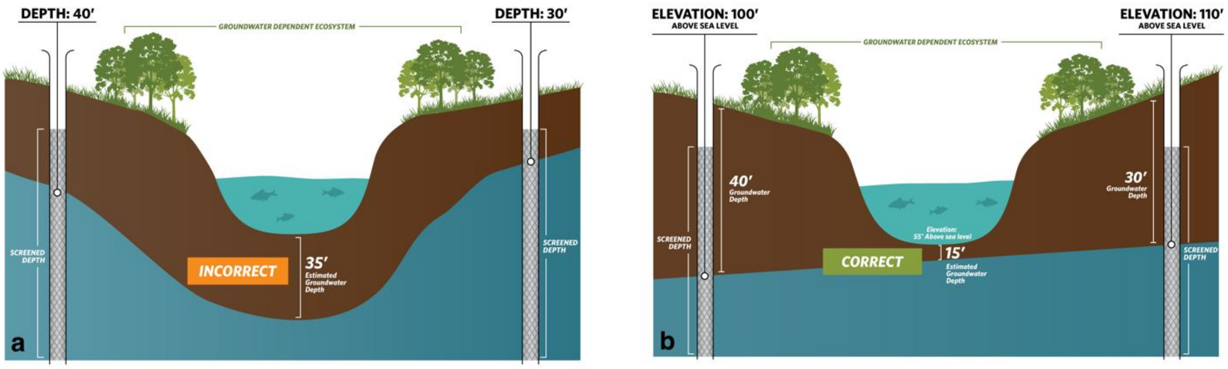

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

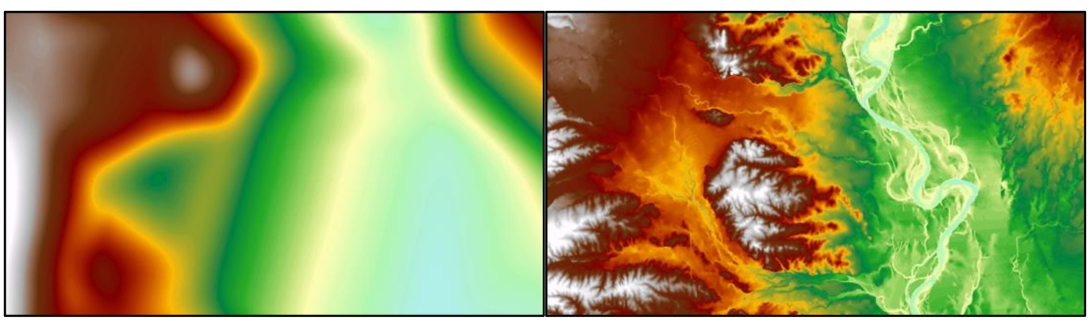

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[16] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

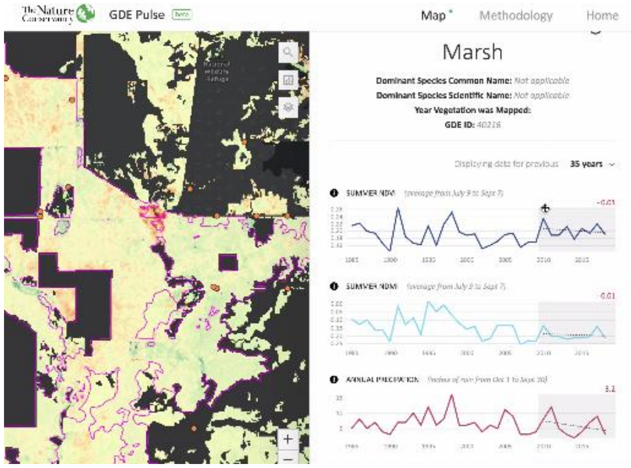
GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Mapping Likely Interconnected Surface Water

The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:

The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

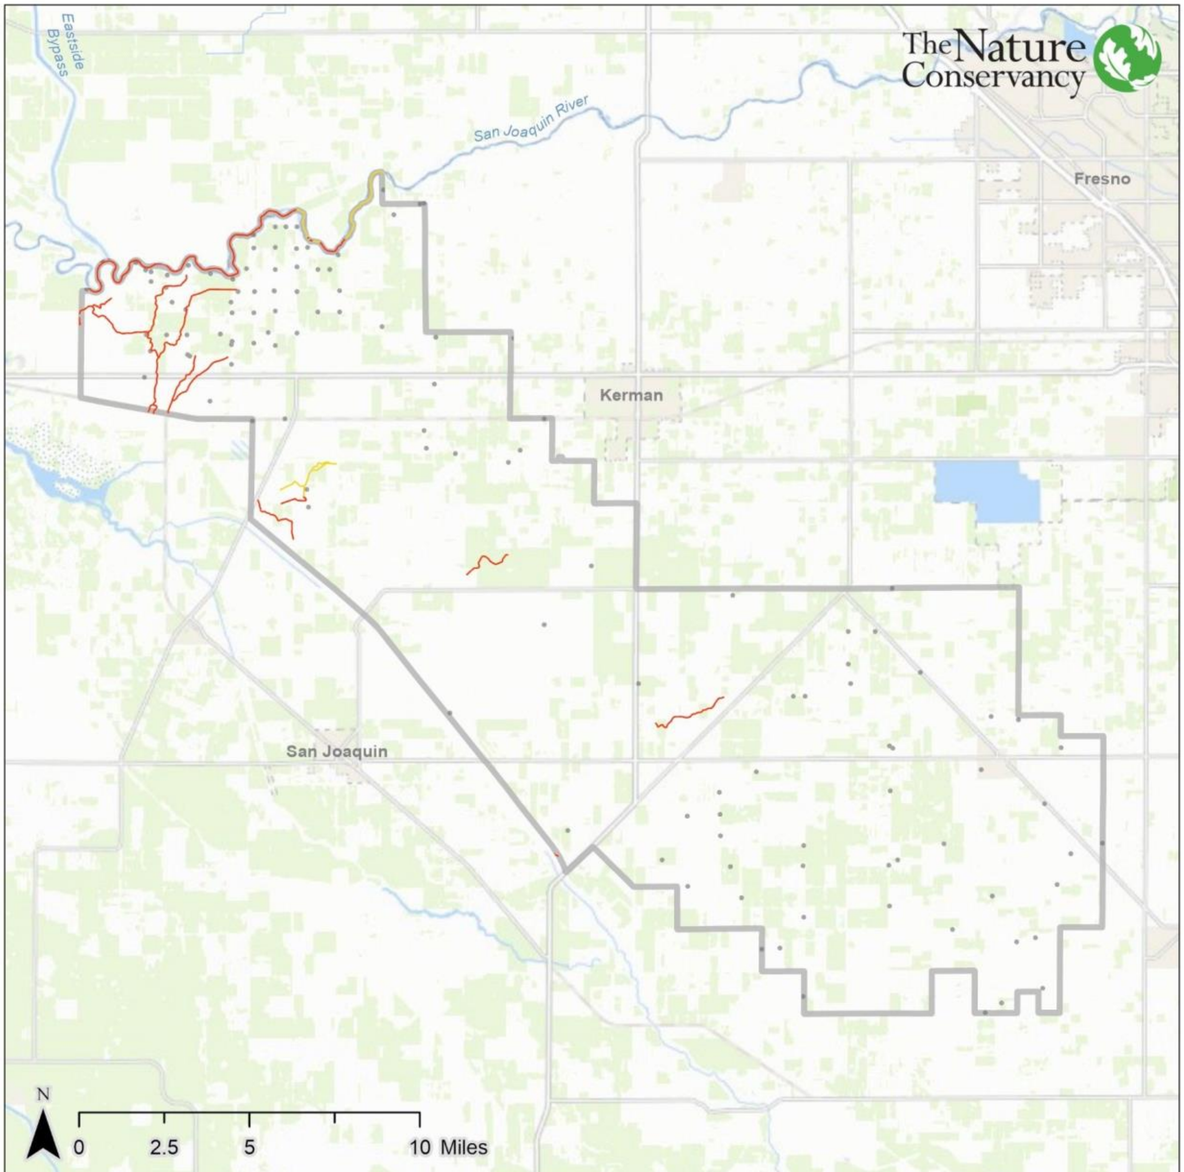
The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2011-2018)

McMullin Area GSA GSP



Legend

- Groundwater Sustainability Agency (GSA)
- No groundwater depth data available
- Rivers and streams with no depth data (0 miles)
- Groundwater Elevation Monitoring Point

Minimum Groundwater Depth

- Connected - Gaining: Groundwater at or above stream surface (0 miles)
- Connected - Losing: Groundwater within 20 feet of stream surface (0 miles)
- Uncertain*: Groundwater within 20-50 feet of stream surface (5.5 miles)
- Likely Disconnected*: Groundwater greater than 50 feet below stream surface (29.2 miles)

**Streams could be connected to riparian or perched aquifers or shallow aquifers that are poorly characterized. More data are needed to confirm disconnected status.*

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Merced Groundwater Subbasin Groundwater Sustainability Plan (GSP)

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Merced Groundwater Subbasin Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be incomplete in addressing environmental beneficial uses and users.

While the GSP addressed environmental beneficial users in some respects, our review finds that portions of the GSP should be remedied before being approved. Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section.

We appreciate that the GSA incorporated a portion of our feedback (5 of 34 comments were addressed), however, we disagree with the components where our feedback was ignored or dismissed. This suggests a limited degree of engagement of environmental beneficial users and could result in a definition of sustainability that is biased towards a limited set of users in the basin. In our experience, the GSP did not "adequately respond(d) to comments that raise credible technical or policy issues with the Plan," (23 CCR §355.4(b)(10).

TNC recommendation: We recommend that DWR require the GSA to prioritize stakeholder engagement, resulting in stakeholder input being incorporated into the plan. Improvements can be achieved through enhancements to the stakeholder engagement plan, partnerships with NGOs and community members, more representative governance and funding decisions.

Interconnected Surface Waters (ISWs) – We are pleased to see that the GSP identified and mapped ISWs, including gaining and losing reaches and accounting for the spatial and temporal variations inherent with California's Mediterranean climate. ISWs are defined based on calculations performed with the MercedWRM model. However, while the Final GSP provides an appendix detailing the MercedWRM, there is little specific information in this document to independently assess the ISWs identified. Specifically, we find the definition of disconnected streams in the text is incorrect because the fact that the groundwater table is below the bottom of the stream bed does not always indicate an unsaturated zone that separates the stream from the groundwater. Our analysis for groundwater levels in the Merced GSP area shows many more interconnected streams including Deadman Creek, Mariposa Slough, and Owens Creek (see Attachment G).

Map and Assessment of potential ISWs:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the Merced Groundwater Subbasin GSP, 91.5 river miles are gaining, 123.9 are losing, and the rest are uncertain or likely disconnected (based on streams with available groundwater depth data). Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

TNC recommendation: We recommend that the calibration of the model is refined to better identify gaining and losing reaches and estimate the quantity and timing of streamflow depletions in the subbasin. We also recommend a more nuanced definition of a disconnected surface water body that would better reflect the expected presence of an unsaturated zone between the surface water and groundwater. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 8,246 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under*

SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not to adequately identify, map and consider GDEs. We believe that this constitutes gaps in meeting plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on the following:

- GDEs were rejected on the basis that groundwater levels were greater than 30-ft at a <u>single point in time</u>. This is a technically incorrect approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30-feet or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and may result in the omission of ecosystems that are groundwater dependent.
- The presence or proximity of surface water, which does not necessarily prove that the plants and animals do not access groundwater. GDEs can simultaneously rely on multiple sources of water (i.e., both groundwater and surface water), or shift their reliance on different sources on an interannual or inter-seasonal basis.
- GDEs located next to net-losing streams were rejected. This selected removal criteria does not necessarily prove that the plants and animals do not access groundwater, as near losing reaches groundwater gradients are close enough to the surface to support ecological communities such as riparian vegetation. Analyzing groundwater levels is a more scientifically robust approach to validate the NC dataset, since GDEs are defined as 'ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface' [23 CCR § 350(m)].

<u>TNC recommendation</u>: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in our BMP guidance document (Attachment D) to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). The GSP only focused on a subset of water use sectors, including urban and agricultural users of groundwater. Within these identified subsectors, we recommend water allocation that incentivizes and promotes demand management. The omission of beneficial environmental users is problematic because key environmental uses of groundwater are not being accounted for as water supply decisions are made using this budget nor will they likely be considered in project and management actions.

<u>TNC recommendation</u>: As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

---

[1] *Available at:* https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Reference is made to a Proposition 68 funding request for addressing data gaps for shallow groundwater monitoring, however, potential well locations and the number of potential wells is not discussed anywhere in the GSP besides a single new monitoring well identified in the El Nido Area near the San Joaquin River. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11
		If NC Dataset *was* used: Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12

<table>
<tr><td rowspan="12"></td><td rowspan="8"></td><td rowspan="2"></td><td>The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).</td><td>13</td></tr>
<tr><td>GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.</td><td>14</td></tr>
<tr><td>If NC Dataset was not used:</td><td>Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.</td><td>15</td></tr>
<tr><td colspan="2">Description of GDEs included:</td><td>16</td></tr>
<tr><td colspan="2">Historical and current groundwater conditions and variability are described in each GDE unit.</td><td>17</td></tr>
<tr><td colspan="2">Historical and current ecological conditions and variability are described in each GDE unit.</td><td>18</td></tr>
<tr><td colspan="2">Each GDE unit has been characterized as having high, moderate, or low ecological value.</td><td>19</td></tr>
<tr><td colspan="2">Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).</td><td>20</td></tr>
<tr><td rowspan="2">2.2.3
Water Budget

Undesirable Results
23 CCR §354.26</td><td colspan="2">For GDEs, hydrological data are compiled and synthesized for each GDE unit:</td><td>30</td></tr>
<tr><td rowspan="3">If hydrological data are available within/nearby the GDE</td><td>Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).</td><td>31</td></tr>
<tr><td>Baseline period in the hydrologic data is defined.</td><td>32</td></tr>
<tr><td>GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.</td><td>33</td></tr>
</table>

			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Merced Subbasin Groundwater Sustainability Plan

The Merced Subbasin GSP dated November 2019 was reviewed by TNC. TNC submitted comments on the Public Draft GSP on August 19, 2019. We reviewed the responses to comments and the text of the Final GSP to determine if changes were made to the Final GSP that addressed TNC's previously submitted comments. Changes have been made in selected sections of the main body of the GSP as well as in Appendix O, where all comments and responses are consolidated. In many cases, responses are provided in Appendix O but no changes to the main body of the GSP have been made. This is noted where appropriate. The GSA response to comments is also provided in Attachment F of this letter. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the Merced Subbasin during the public comment period, and states whether or not they were addressed in the Final GSP *[as green text within brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

Section 1.2.5 Beneficial Uses and Users p. 1-40
(Checklist Item 1)
[This comment was partly addressed. This section has been modified to note environmental interests as a subheading. The following NGOs are added to the list: Audubon California; East Merced Resource Conservation District / Sustainable Conservation; River Partners. No additional information is provided on the natural communities and no reference is made to the freshwater species list. Appendix O describes the stakeholder selection process in the region, but the identification of environmental stakeholders is not specifically described.] The environment is listed as one of the beneficial users of groundwater in the Subbasin, but few details are given. The US Fish and Wildlife is listed as operating several wildlife refuges supported by groundwater, as shown in Figure 1-7 (p. 1-20), along with state parks. A statement is made that there are other wetlands and GDEs that exist mostly in the western part of the subbasin, but they are not specified.

The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. To identify environmental users, **please refer to the following**:

- Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/
- The list of freshwater species located in the Merced. Subbasin in **Attachment C** of this letter. Please take particular note of the species with protected status.
- Lands that are protected as open space preserves, habitat reserves, wildlife refuges, etc. or other lands protected in perpetuity and supported by groundwater or interconnected surface waters should be identified and acknowledged.

The stakeholder outreach process is described, and include outreach to federal, state, and local agencies, but did not appear to engage environmental groups. **Please note if any environmental groups were contacted and were enlisted in the GSP development process.**

<u>Section 1.2 Plan Areas p. 1-13 through 1-38</u>
<u>(Checklist Item 2)</u>

[This comment was partly addressed. This section has been modified to refer to a map of the surface water stations in Chapter 4. No reference is made to other plans, such as HCPs and NCCPs in the subbasin.] The jurisdictional boundaries and water use management and existing monitoring programs are adequately described. The land use designations do not show types of crops. Only federal and state parks are shown on Figure 1-7 (p. 1-20). The general and land use plans are adequately described. **Surface water gauging is described for the three major creeks; a map showing the locations would be helpful. Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin should be added and noted if they are associated with critical, GDE and/or ISW habitats.**

<u>Section 2.1.3.3 Surface Water p. 2-9 through 2-12</u>
<u>(Checklist Item 3)</u>

[This comment was partly addressed. A limited amount of information is provided, but there is no systematic summary of instream flow requirements in the different creeks, except the following statement on page 1-41: "Since 2000, Merced River releases by MID for the Vernalis Adaptive Management Plan to facilitate the migration of juvenile Chinook salmon have been approximately 60,000 AFY."] The regulation of surface waters by dams and reservoirs is described for each of the major rivers in Section 2.1.3.3 Surface Waters. Past examples of in-stream flows are given on page 1-40 for the Merced River, by the Merced Irrigation District. In-stream flow requirements in each of the rivers/streams including the amount, time of year when the flow minimum is specified, the duration, the freshwater fish species for which it applies, associated permits that set forth the requirements, and the regulating agency setting forth the compliance requirements. **Please provide a list of the current in-stream flow requirements for chinook salmon and other threatened and endangered fish species and other requirements to protect habitat on the Merced and San Joaquin Rivers and the other creeks.**

<u>Section 1.2.3.3 Well Permitting p.138</u>
<u>Checklist Item 4</u>

[No additional clarification is provided in the GSP.] Merced County established a well permitting system for new, replacement, back-up, and De Minimus wells in 2015. It is not clear if this requirement covers monitoring wells, unless they are classified as De Minimus wells. The permit includes property setback distances, which may apply to surface water. The City of Merced also enforces well standards that apply to all new and existing water wells, monitoring wells, cathodic protection wells, test wells and those exploratory holes deeper than twenty feet within the jurisdictional boundaries of the city. The City of Merced directs permittees to DWR standards for

wells. **Please clarify the permitting requirements for monitoring wells and how they will be coordinated with the GSP.**

Section 2.1.6.2 Bottom of the Merced Basin p. 2-39
(Checklist Item #5)

[This comment was addressed. This clarifying information is provided on page 2-43 of the Final GSP: "A well depth analysis completed in March 2018 found that, based on information in Merced County's well permit database, 56 wells (approximately 4% of wells with data) extended below the bottom of the basin as defined above, primarily located along the central portion of the County just east of the San Joaquin River (Woodard & Curran, 2018b). The quality of water produced from these wells is not known, and no data are available to show that the wells are actively used."] The base of freshwater, defined as specific conductance > 3,000 micromhos/cm, is used as the bottom of the basin. Because the depth varies with location, a map is provided as Figure 2-28 (p. 2-40). The depth of this boundary is provided in some areas of the geologic cross-sections, but not others. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the definition of the basin bottom.** This will prevent the possibility of extractors with wells deeper than the basin boundary (defined by the base of freshwater) from claiming exemption from SGMA due to a well residing outside the vertical extent of the basin boundary. **Please check that active wells used for domestic or public water supply or agricultural wells are not deeper than the base of freshwater.**

Section 2.2.1.2 Current Groundwater Conditions p. 2-63 through 2-29
(Checklist Item #6)

[No GSP changes made in this section.] The number of wells used to describe the groundwater elevations for each aquifer is sparse. For example, there were only eight wells used for the spring 2017 elevation measurements (Figure 2-44 p. 2-64) for the Above the Corcoran Clay aquifer and six for fall 2017 elevation for the Above the Corcoran Clay aquifer (Figure 2-47 p. 2-67). Additional wells have been included in the GSP Monitoring Program, as stated on p. 4-2, "The Merced Subbasin GSP groundwater level monitoring network totals 50 wells from the CASGEM program. This includes 13 wells in the Above Corcoran Clay Principal Aquifer, 16 wells in the Below Corcoran, and 21 wells in the Outside Corcoran. **Additional monitoring wells with appropriate screened intervals should be installed and added as the funding allows.**

Section 2.1.7.2 Principal Aquifers and Aquitards
(Checklist Item 6)

[No GSP changes made in this section.] The three principal aquifers have been combined from the original five designations. The three aquifers are shown in a schematic diagram (Figure 2-36 p. 52) and the general characteristics are discussed (p. 2-52 and 2-53). The shallow aquifers are not described in sufficient detail to show where GDEs are likely and the places with interconnected surface water. **Please expand the discussion of shallow groundwater and discuss any**

information regarding vertical groundwater gradients across the principal aquifers.

Section 2.1.4 Geologic Formations and Stratigraphy
(Checklist Item 7)

[No GSP changes made in this section.] The geologic cross-sections, Figures 2-13 through 2-17 and Figure 2-19 through 2-22 (p. 2-24 and 2-27 and 2-29 and 2-32, respectively), show the full depth of the basin and do not highlight the shallow aquifers. **Cross-sections along the San Joaquin and Merced Rivers showing the relationship between the rivers and the shallow aquifers would be helpful**. **The near-surface cross sections should provide details that depict the conceptual understanding of shallow groundwater and stream interactions at different locations, including perched aquifers**.

Section 2.2.6 Interconnected Surface Waters p. 108
(Checklist Items 8, 9 and 10)

[This comment was partly addressed. Documentation for the MercedWRM model is now presented in Appendix D. However, there is no information in this appendix to allow an evaluation of the gaining and losing streams. There is no calibration data reported on streamflows. Furthermore, the concept of "interconnected waters" is not referred to at all in the modeling report in Appendix D, although in other parts of the GSP it is stated that MercedWRM model is used to quantify interconnected surface waters.] A map showing gaining and losing streams was provided in Figure 2-9 (p. 2-15) as determined using the Merced Water Resources Model (MercedWRM). The report stated that no field studies had been conducted to confirm the designations and the documentation of the model was not provided in this report (Appendix D). Therefore, no estimates of surface water depletions by water year type were made. **Please provide the documentation for the model and how the gaining and losing streams were determined.**

Section 2.2.7 GDEs p. 2-109
(Checklist Item 10-15)

SGMA requires that all beneficial uses and users, including GDEs, be considered in the development and implementation of GSPs (Water Code §10723.2). The GSP Regulations include specific requirements to identify (map) GDEs and consider them when determining whether groundwater conditions are having potential effects on beneficial uses and users. SGMA also requires an assessment of whether sustainable management criteria (including minimum thresholds and measurable objectives) may cause adverse impacts to beneficial uses, including GDEs, and that monitoring networks are designed to detect such impacts. Therefore, mapping GDEs is a critical first step for incorporating environmental considerations into GSPs.

- It appears that the preliminary desktop analysis, completed by Woodard & Curran and documented in the draft GSP, resulted an excessive elimination of the NC dataset polygons mapped in the Merced Subbasin. In particular, the methods used to confirm whether or not polygons in the NC Dataset are connected to groundwater in the Merced Subbasin are highly flawed. Here we debunk the scientific insufficiencies in the methodology used:
    1. *Areas with depth to groundwater greater than 30 feet in Spring 2015.*

a. *[No changes to this section were made in response to above comment. The screening is still performed using Spring 2015 data. Furthermore, there is no change in the methodology used to identify and remove GDE areas from consideration. In Appendix O, it is stated that the methodology combined the NCCAG database with "additional local data and knowledge," but no further details are provided.]* While depth to groundwater levels within 30 feet are generally accepted as being a proxy for confirming that polygons in the NC dataset are connected to groundwater, it is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from <u>one point in time</u> (e.g., Spring 2015) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Based on a study we recently submitted to Frontiers in Environmental Science Journal, we've observed riparian forests along the Cosumnes River to experience a range in groundwater levels between 1.5 and 75 feet over seasonal and interannual timescales. Seasonal fluctuations in the regional water table can support perched groundwater near an intermittent river that seasonally runs dry due to large seasonal fluctuations in the regional water table. While perched groundwater itself cannot directly be managed due to its position in the vadose zone, the water table position within the regional aquifer (via pumping rate restrictions, restricted pumping at certain depths, restricted pumping around GDEs, well density rules) and its interactions with surface water (e.g., timing and duration) can be managed to prevent adverse impacts to ecosystems due to changes in groundwater quality and quantity under SGMA. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network.**
b. *[No additional clarification provided in Final GSP.]* **Please confirm that wells screened in the Shallow and Leaky intermittent principal aquifers located <u>above the Corocoran Clay Layer</u> are being used to verify whether NCCAGs are actual GDEs.** According to Figure 2-39, the majority of wells in the area in between Route 140, Route 59, and the San Joaquin River where NCCAGs were not identified as GDEs due to "depth to water" (Figure 2-86); however the wells located in this area are predominantly irrigation

and domestic wells screened in the principal aquifers BELOW the Corocoran Clay Layer. Using "depth to groundwater" measurements from confined aquifers is mapping piezometric head of the confined aquifer and not detecting groundwater conditions in the principal aquifers of the unconfined aquifer that are supporting the ecosystem. If there is insufficient groundwater level data in the principal aquifers above the Corocoran Clay layers, then the NCCAGs in these areas should be included as GDEs in the GSP until data gaps are reconciled in the monitoring network.

c. *[No additional detail provided on the depth calculation.]* Please provide more details on how depth to groundwater contour maps were developed:
    i. Are the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons to reflect local conditions relevant to ecosystems?
    ii. Are the wells used for interpolating depth to groundwater screened within the surficial unconfined aquifer and capable of measuring the true water table? (see comment b above)
    iii. Is depth to groundwater contoured using **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape? This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[2] to estimate depth-to-groundwater contours across the landscape. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to contour depth to groundwater.

d. *[No GSP changes made in response to this comment.]* Spring 2015 is after the SGMA benchmark date of January 1, 2015. **Please rely on groundwater condition data prior to the SGMA benchmark date.**

e. *[No GSP changes made in response to this comment.]* Please use care when considering rooting depths of vegetation. While Valley Oak (*Quercus lobata*) have been observed to have a max rooting depth of ~24 feet (https://groundwaterresourcehub.org/gde-tools/gde-rooting-depths-database-for-gdes/), rooting depths are likely to spatially vary based on the local hydrologic conditions

[2] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

available to the plant. Also, max rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not like to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths. In addition, while it is likely to be true that shallow water availability is necessary to support the recruitment of saplings, hydraulic lift of groundwater to shallow depths has been observed in *Quercus* spp. Research on the symbiotic relationships between species and offspring is still emerging, but the assumption that a groundwater depth of 25 feet is "unlikely to support recruitment of new oak seedlings" is an unsubstantiated claim and falsely considered to be "conservative". This approach is not "conservative" and results in the elimination of more NC polygons because it negates the fact that there may be mature tree species that are likely connected to groundwater. Regardless of life stage, if any plant or animal species in the NC polygons are connected to groundwater, then it needs to be mapped as a GDE. The evaluation of potential effects on GDEs (e.g., the likelihood that regeneration is not occurring in the GDE due to groundwater levels being too deep for saplings) is to be performed when defining undesirable results in the Sustainable Management Criteria section of GSP, not the Basin Setting section.

2. *Habitat areas with supplemental water*
    a. *[No GSP changes made in response to this comment.]* The application of supplemental water to managed wetlands <u>does not preclude</u> the possibility that NC polygons could be accessing groundwater in addition to the supplied water. In the scientific literature, it is generally acknowledged that GDEs can rely on groundwater for <u>some or all</u> of its requirements. GDEs can rely on multiple water sources simultaneously and at different temporal/spatial scales (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow). SGMA defines GDEs as "ecological communities and species that depend on groundwater <u>emerging from aquifers</u> or on groundwater <u>occurring near</u> the ground surface". Hence, **we recommend that depth to groundwater contour maps are used to identify whether a connection to groundwater exists for the Managed Wetlands in the Merced Subbasin. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.**
3. *Areas adjacent to irrigated fields*
    a. *[No GSP changes made in response to this comment.]* SGMA defines GDEs as "ecological communities and species that depend on

groundwater emerging from aquifers or on groundwater occurring near the ground surface". **We recommend that depth to groundwater contour maps are used to identify whether a connection to groundwater exists for the NC Dataset polygons adjacent to irrigated fields in the Merced Subbasin. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.**

b. *[No GSP changes made in response to this comment.]* GDEs can rely on multiple water sources – including shallow groundwater receiving inputs from irrigation return flow from nearby irrigated fields - simultaneously and at different temporal/spatial scales. Groundwater basins can be comprised of one continuous aquifer or multiple aquifers stacked on top of each other. Basins with a stacked series of aquifers may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow principal aquifers, that support springs, surface water, and groundwater dependent ecosystems. **NC polygons adjacent to irrigated land can still potentially be reliant on shallow groundwater aquifers, thus excluding them based on their proximity to irrigated fields is inadequate.**

4. *Areas depending on adjacent losing surface water bodies*

   a. *[No GSP changes made in response to this comment.]* While losing conditions occur when groundwater levels are lower than the stage in the stream, the degree to which losing conditions occur will depend on the groundwater level gradient between them. Losing conditions also vary in time, especially over different seasons. Even if a stream or river reach is losing, the riparian vegetation may still be accessing groundwater, and hence be identified as a GDE. **We highly recommend that depth to groundwater levels under the NC polygons be used as the evaluation criteria, since access to groundwater could be occurring in/near losing reaches. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.** If riparian vegetation in losing reaches are 100% of the time using surface water (especially if the groundwater is consistently deep), it is not a GDE.

   b. *[This comment was partly addressed. Although model documentation is provided, the graphical information is not sufficiently detailed to allow an independent assessment of the areas excluded.]* Areas within 300 feet of losing streams identified by the model, MERCEDWRM, were eliminated. The distance of 300 feet seems excessive and may have eliminated some areas prematurely. The documentation of the model was not included in the draft report, Appendix D, so this information could not be verified.

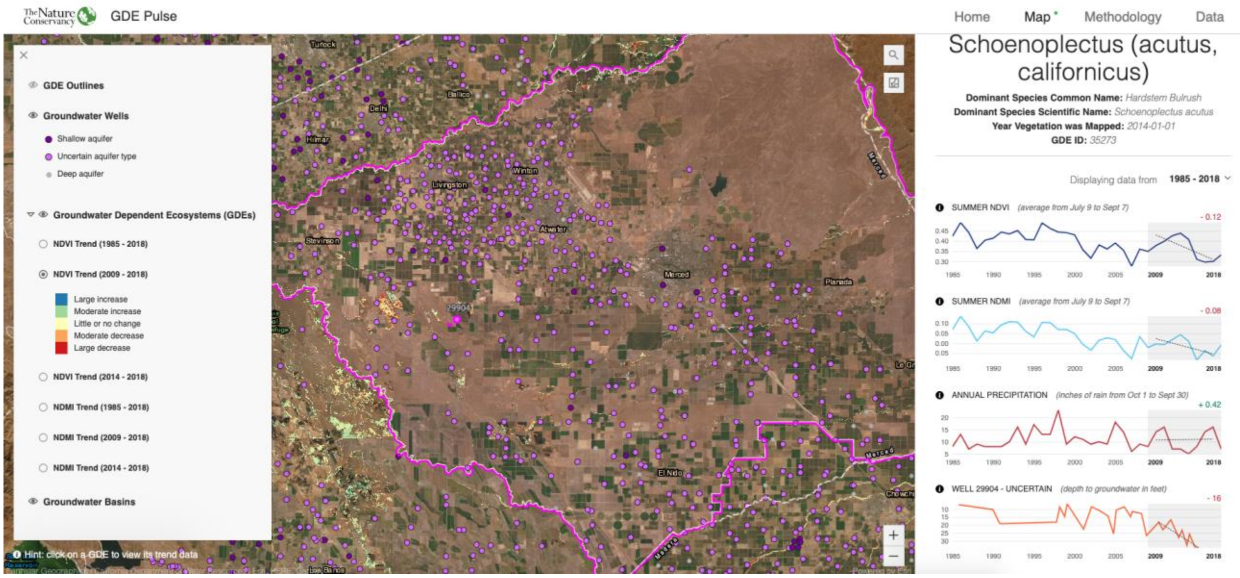
5. *Areas of vernal pool complexes*
    a. *[No GSP changes made in response to this comment.]* While we generally agree that vernal pools are shallow pockets of groundwater that are not directly connected or associated with principal aquifers, **please included a short description on whether or not the vernal pool complexes mapped in the DFW 1989-1998 dataset are consistent with information collected in the HCM and groundwater conditions in the surficial aquifers (e.g., shallow and intermittent leaky aquifers above the Corocoran Clay Layer).**

- *[These maps were not modified in the Final GSP.]* The NC dataset is a starting point for GSAs to identify GDEs in their basin. **Please map the original NC dataset on Figures 2-86, 2-87, and 2-88 (p. 2-111, 2-112, and 2-113) and document which polygons were added (and what local sources were used to identify them), removed (and the removal reason), and kept (from the original NC dataset). The basin's GDE shapefile, which is submitted via the SGMA Portal, should also include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).**

Section 3.37 GDE p. 2-109 through 2-112

Checklist Items 16-20)

- *[This comment was not addressed in the Final GSP. No new information provided on historical and current conditions in the Final GSP, but this is identified as future work to be done during the preparation of the first Annual Report (Section 7.6).]* No information was given on the historical or current groundwater conditions in the GDEs or the ecological conditions present. **Please provide groundwater data for historical and current conditions near the GDEs or identify as a data gap. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI).** Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in Merced Subbasin:



- *[This comment was not addressed. No additional information is provided in the GSP, and no indication provided that this will be addressed in future work.]* The vegetation species were not ranked as having a high, moderate or low value and no inventory of the vegetation types or habitat types were provided. **Please identify whether any endangered or threatened freshwater species of animals and plants or areas with critical habitat were found in any of the GDEs.** The list of freshwater species located in the Merced Subbasin in **Attachment C** of this letter.

<u>Section 2.3 Water Budget Information p. 2-113</u>
<u>(Checklist Item 21-22)</u>

[This comment was partly addressed. Additional documentation was provided on the water budget as part of the model documentation in Appendix D.] The water budget for the surface water components did not include an explicit evapotranspiration term, but the following footnote was included as an explanation to Table 2-14 (p. 2-121 to 2-122). "Other flows is a closure term that captures the stream and canal system include gains and losses not directly measured or simulated within IWFM. Some of these features include but may not be limited to direct precipitation, evaporation, unmeasured riparian diversions and return flow, temporary storage in local lakes and regulating reservoirs, and inflow discrepancies resulting from simulating impaired flows." Riparian uptake from streams and evapotranspiration was included in the Land System Budget Table 2-15 (p. 2-123 to 2-124). The groundwater budget (Table 2-16 p. 2-125 and 2-126) did not include an explicit evapotranspiration term but included the following footnote "Other flows within the groundwater system including temporary storage in the vadose zone, and root water uptake from the aquifer system." The water budgets were calculated by the model, MercedWRM, and without the documentation the water budget is uncertain. **Please provide a more complete description of the budget and the full model documentation in Appendix D.**

Section 3.1 Sustainability Goal p, 3-1
(checklist Items 23-25)

[This comment was not addressed. No change made in response to this comment in the main body of the GSP. This is also not identified nor addressed as a comment or response in Appendix O.] The sustainability goal is stated as "Achieve sustainable groundwater management on a long-term average basis by increasing recharge and / or reducing groundwater pumping, while avoiding undesirable results" (p. 3-1). The report does not provide details on stakeholders involved in the goal selection process. The statement refers to "undesirable results" but does not mention GDEs, specifically. The goal appears to be directed toward reducing the groundwater overdraft and reducing the chance of wells going dry. The goal does not make a distinction between the pre-SGMA period and later years. **Please clarify the sustainability goal and expand it to pertain to protection of GDE, ISWs and critical habitats.**

Section 3.3.3 Measurable Objectives and Interim Milestones p, 3-4
(Checklist Item 26)

[No GSP changes made in response to this comment.] The measurable objectives addressed only the representative monitoring wells and was set at 25 feet above the minimum threshold. GDEs were not considered. **Please expand the Measurable Objectives to include protection of the environmental health of GDEs and ISWs.**

Section 3.3.2 Minimum Thresholds p. 3-4
(Checklist Item 27-29)

[No GSP changes made in response to this comment.] The minimum threshold was set at each of the representative monitoring wells. The level was defined as "The minimum threshold for groundwater levels was defined as the construction depth of the shallowest domestic well within a 2-mile radius." p. 3-5
Thus, GDEs were not considered. **Please explain whether any adverse impacts to GDEs are expected and if changes to the minimum threshold should be made.**

[No GSP changes made in response to this comment.] Chronic lowering of groundwater was considered by proxy only for the Merced River and San Joaquin River, not for the other creeks in the Merced Subbasin. **Please identify areas on rivers or creeks where depletions are expected and if the minimum threshold should be changed.**

Section 3.3.1 Undesirable Results p. 3-3
(Checklist Items (30-46)

- *[No GSP changes made in response to this comment.]* Undesirable results are defined as follows: "For the Merced Subbasin, an undesirable result for declining groundwater levels is considered to occur during GSP implementation when November groundwater levels at greater than 25% of representative monitoring wells (at least 7 of 25) fall below their minimum thresholds for two consecutive years where both years are categorized hydrologically as below normal, above normal, or wet" (p.3-3). GDEs are not specifically addressed. No hydrologic or biological data are compiled for the GDEs and data gaps are not described. Potential impacts on the GDEs are not described. **For existing GDEs, please provide hydrologic and biological data for current conditions and describe how susceptible they are to future impacts.**

- *[No specific GSP change made in response to this comment, although the use of the GDE Pulse is noted in Chapter 7 in the context of developing future annual reports.]* **Please provide more specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs.** The definition of 'significant and unreasonable' is a qualitative statement that is used to describe when undesirable results would occur in the basin, such that a minimum threshold can be quantified. Potential effects on all beneficial users of groundwater in the basin need to be taken into consideration. According to the California Constitution Article X, §2, water resources in California must be "put to beneficial use to the fullest extent of which they are capable". **Please identify appropriate biological indicators that can be used to monitor potential impacts to environmental beneficial users due to groundwater conditions. Refer to Appendix E of this letter for an overview of a free, new online tool for monitoring the health of GDEs over time.**

Section 4.5.6 Data Gaps p. 4-13
(Checklist Item #47)

[See note below on additional monitoring well construction.] Three regions where monitoring wells are missing or scarce are shown in Figure 4-6 (p. 4-14). These areas include:

> "1. Data Gap #1: Located northwest of Merced and northeast of Atwater, this area contains relatively fewer existing wells, which often have limited construction information, and the wells are generally privately owned and require coordination with well owners to obtain permission and data.
> 2. Data Gap #2: Located along the western edge of the Subbasin, this area has virtually no known wells; overall well coverage needs to be enhanced through outreach to well owners to identify wells that can be used for monitoring purposes.
> 3. Data Gap #3: Located along the southern portion of the Subbasin just east of Data Gap #2, there are known potential wells to monitor but acquiring data from these wells is associated with technical or funding issues. These wells are primarily located within a federal wildlife refuge."

Aside from these areas, there are limited wells close to the Merced and San Joaquin Rivers to track conditions near potential GDEs. **Greater effort should be directed toward obtaining full well construction information in all areas, but especially in the areas with GDEs and then selecting appropriate wells for monitoring.**

Section 4.10 Depletions of Interconnected Surface Water Monitoring Network p, 4-30
(Checklist Item 48)

[This comment was partly addressed, and indirectly in an appendix; it would be better to make the change in the main body of the GSP. Currently, Appendix O

provides the following update on shallow groundwater monitoring: "Shallow groundwater monitoring, particularly in the El Nido area and near the San Joaquin River, is identified as a critical data gap in the GSP. The GSP implementation section has been revised to indicate that new monitoring well sites in areas near likely GDEs should include a very shallow well at the same location, to the extent funding and logistics allow. The GSAs are also requesting additional funding from the state to aid in addressing data gaps through a grant program established by the California Drought, Water, Parks, Climate, Coastal Protection, and Outdoor Access for All Act of 2018 (Proposition 68). A multi-level monitoring well is already planned for installation at the fire station in El Nido as a result of Sustainable Groundwater Planning Grant Program Round 2 funding by the Water Quality, Supply, and Infrastructure Improvement Act of 2014 (Proposition 1)."] The stream gauges used to support interconnected stream monitoring are listed in Table 4-10 and shown in Figure 4-9 (p. 4-32 and 4-33, respectively). The GSP states on page 4-35 that "The understanding of depletions of interconnected surface water could be improved through additional depth-discrete groundwater elevation data near some rivers and streams and some NCCAGs." **The addition of clusters of multi-depth wells near the known interconnected surface waters should be given a high priority.**

Section 4.1 Monitoring Network Objectives p, 4-1
(Checklist Item 49)

[No change made in response to this comment in the GSP, although the use of the GDE Pulse tool is referred to for future Annual Reports.] One of the stated objectives of the monitoring program is "Monitoring impacts to the beneficial uses or users of groundwater." (p. 4-1) There is no reference to use of biological data for monitoring potential impacts to the GDEs or to the combined use of hydrologic and biological data. Hydrologic and biological data should be obtained around existing GDEs. Remote imaging can provide a useful tool for monitoring ecosystem health of GDEs and ISWs. **Please clarify the potential use of imagery as a monitoring tool and expand it to monitoring surface indicators of ISW and GDE ecosystem health. Please describe how GDEs will be monitored to avoid or minimize impacts from both a hydrologic and biological standpoint.**

Section 6.3 Projects p. 6.6
(Checklist Item #50-51)

[No change made in the GSP in response to this comment. In Appendix O it is stated that "The existing prioritization criteria was intended to encompass and is consistent with the suggested revision of prioritization description. This change to the text would not alter the results of current or future project prioritization."] A process was conducted by the three GSAs and stakeholders to select 12 projects. The projects are listed in Table 6-3. Only a general way of evaluating each project is given. Up to 50 future potential projects, listed in Table 6-6 Projects Running List for Reference, and may be implemented as priorities and funding change. None of the 12 selected projects are expected to directly benefit GDEs. **Please explain how the groundwater recharge projects (Project #1, #4, and #10) could benefit GDEs or a location near the GDEs and how the projects will be evaluated.**

Attachment C

Freshwater Species Located in the Merced Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Merced Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[4] as well as on The Nature Conservancy's science website[5].

Scientific Name	mmon Name	Legally Protected Species		
		Federal	State	Other
Birds				
Haliaeetus leucocephalus	Bald Eagle	Bird of Conservation Concern	Endangered	
Himantopus mexicanus	Black-necked Stilt			
Icteria virens	Yellow-breasted Chat		Special Concern	BSSC - Third priority
Ixobrychus exilis hesperis	Western Least Bittern		Special Concern	BSSC - Second priority
Limnodromus scolopaceus	Long-billed Dowitcher			
Lophodytes cucullatus	Hooded Merganser			
Megaceryle alcyon	Belted Kingfisher			
Mergus merganser	Common Merganser			
Mergus serrator	Red-breasted Merganser			
Numenius americanus	Long-billed Curlew			
Numenius phaeopus	Whimbrel			
Nycticorax nycticorax	Black-crowned Night-Heron			
Oxyura jamaicensis	Ruddy Duck			
Pandion haliaetus	Osprey		Watch list	
Pelecanus erythrorhynchos	American White Pelican		Special Concern	BSSC - First priority

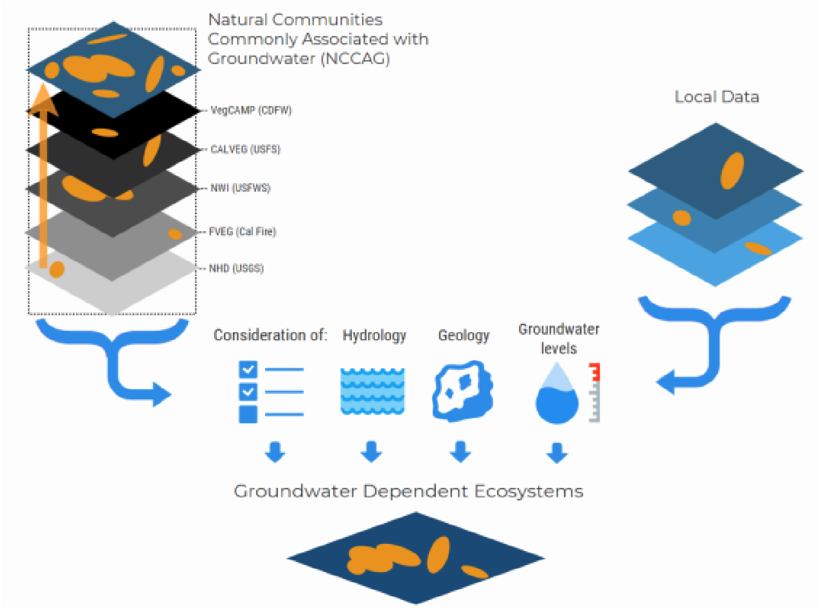
July 2019

IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48

---

[6] *NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/*

[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

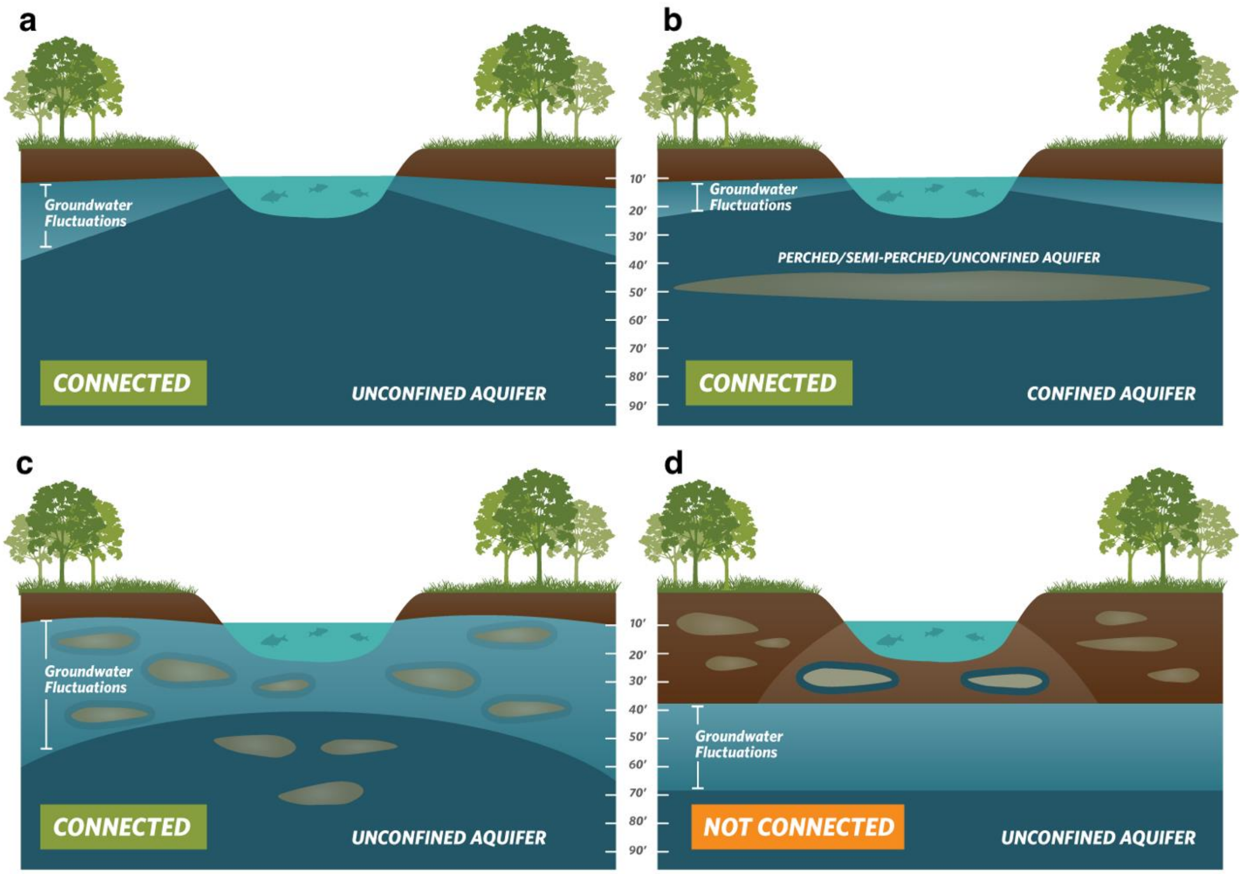

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

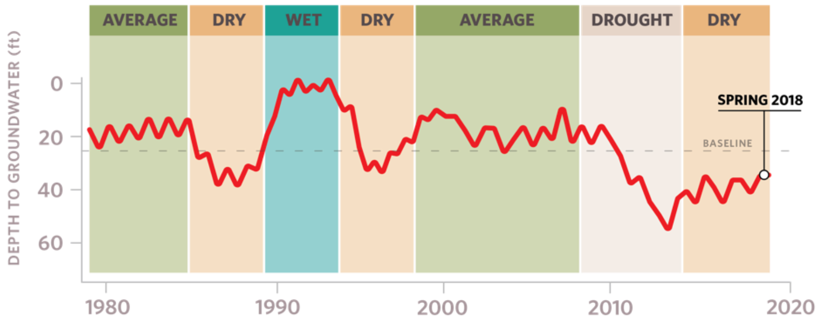

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

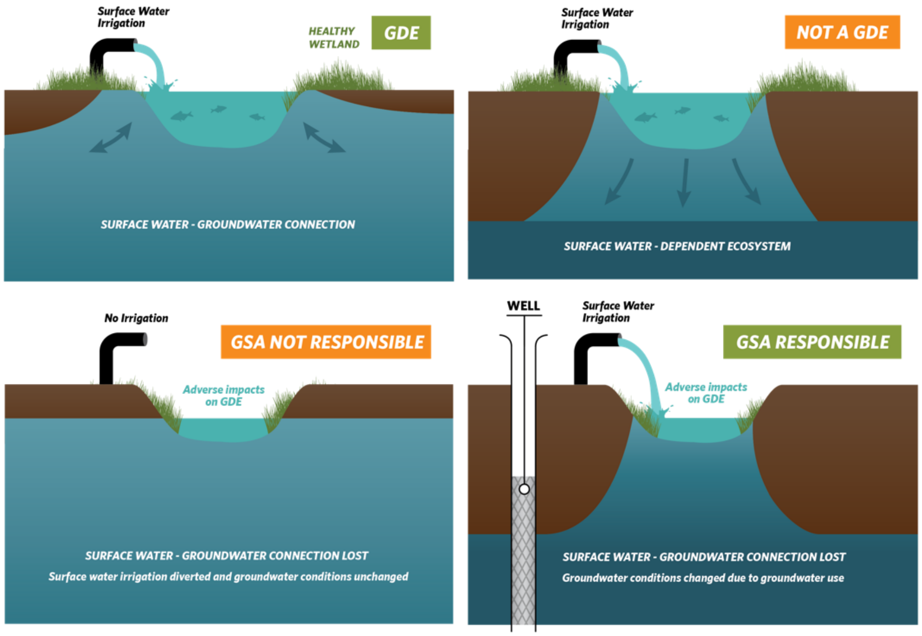

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

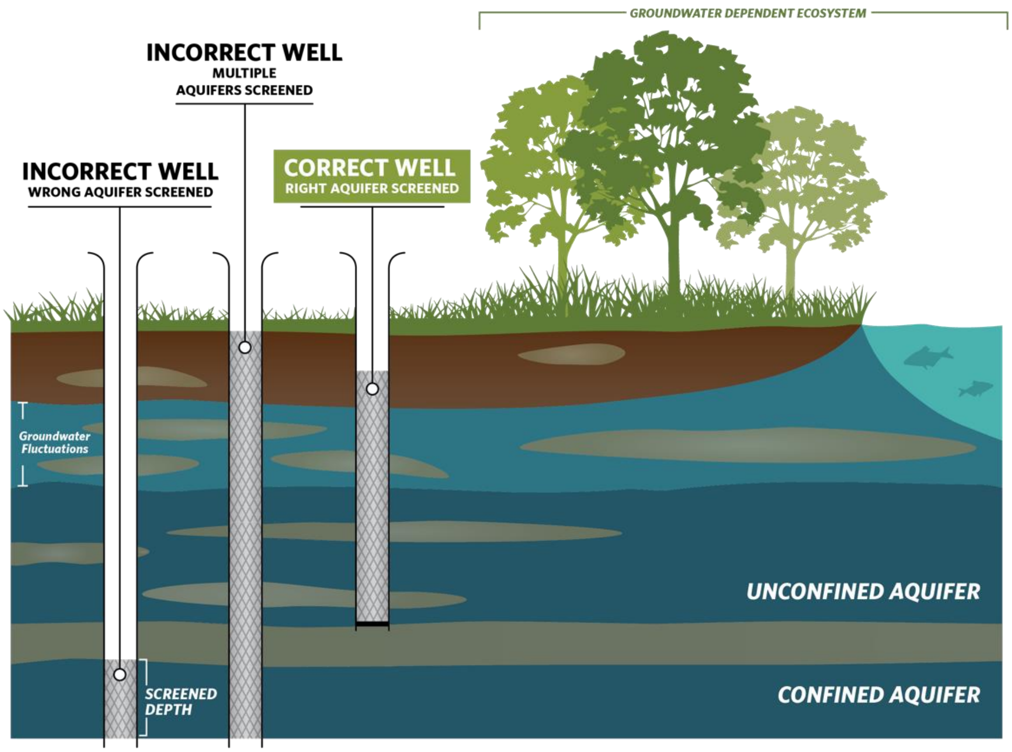

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

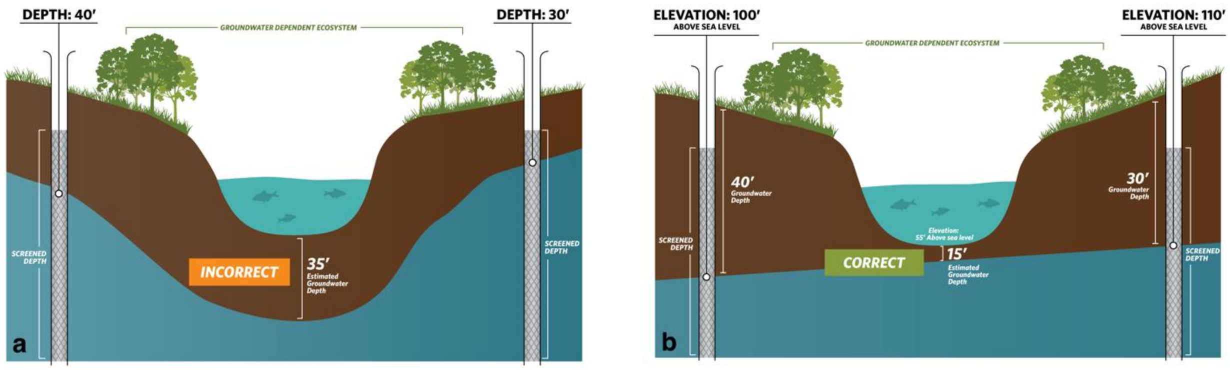

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

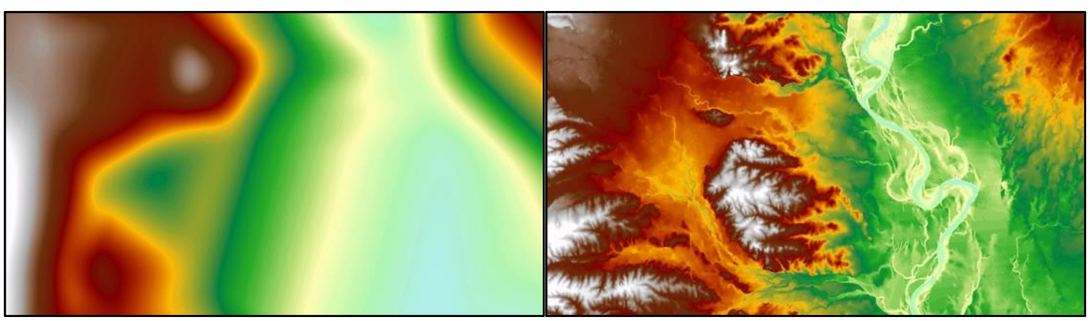

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

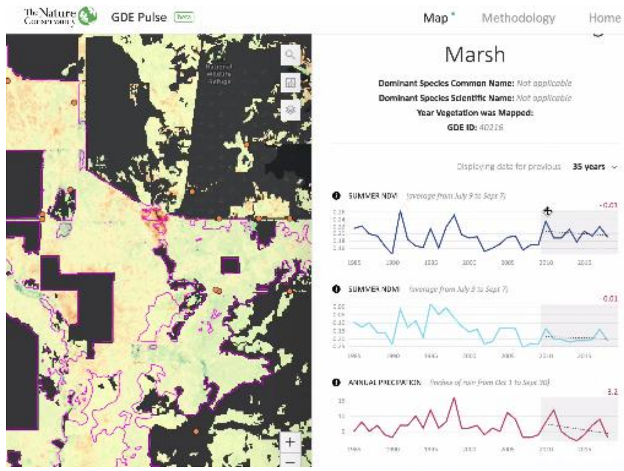
GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

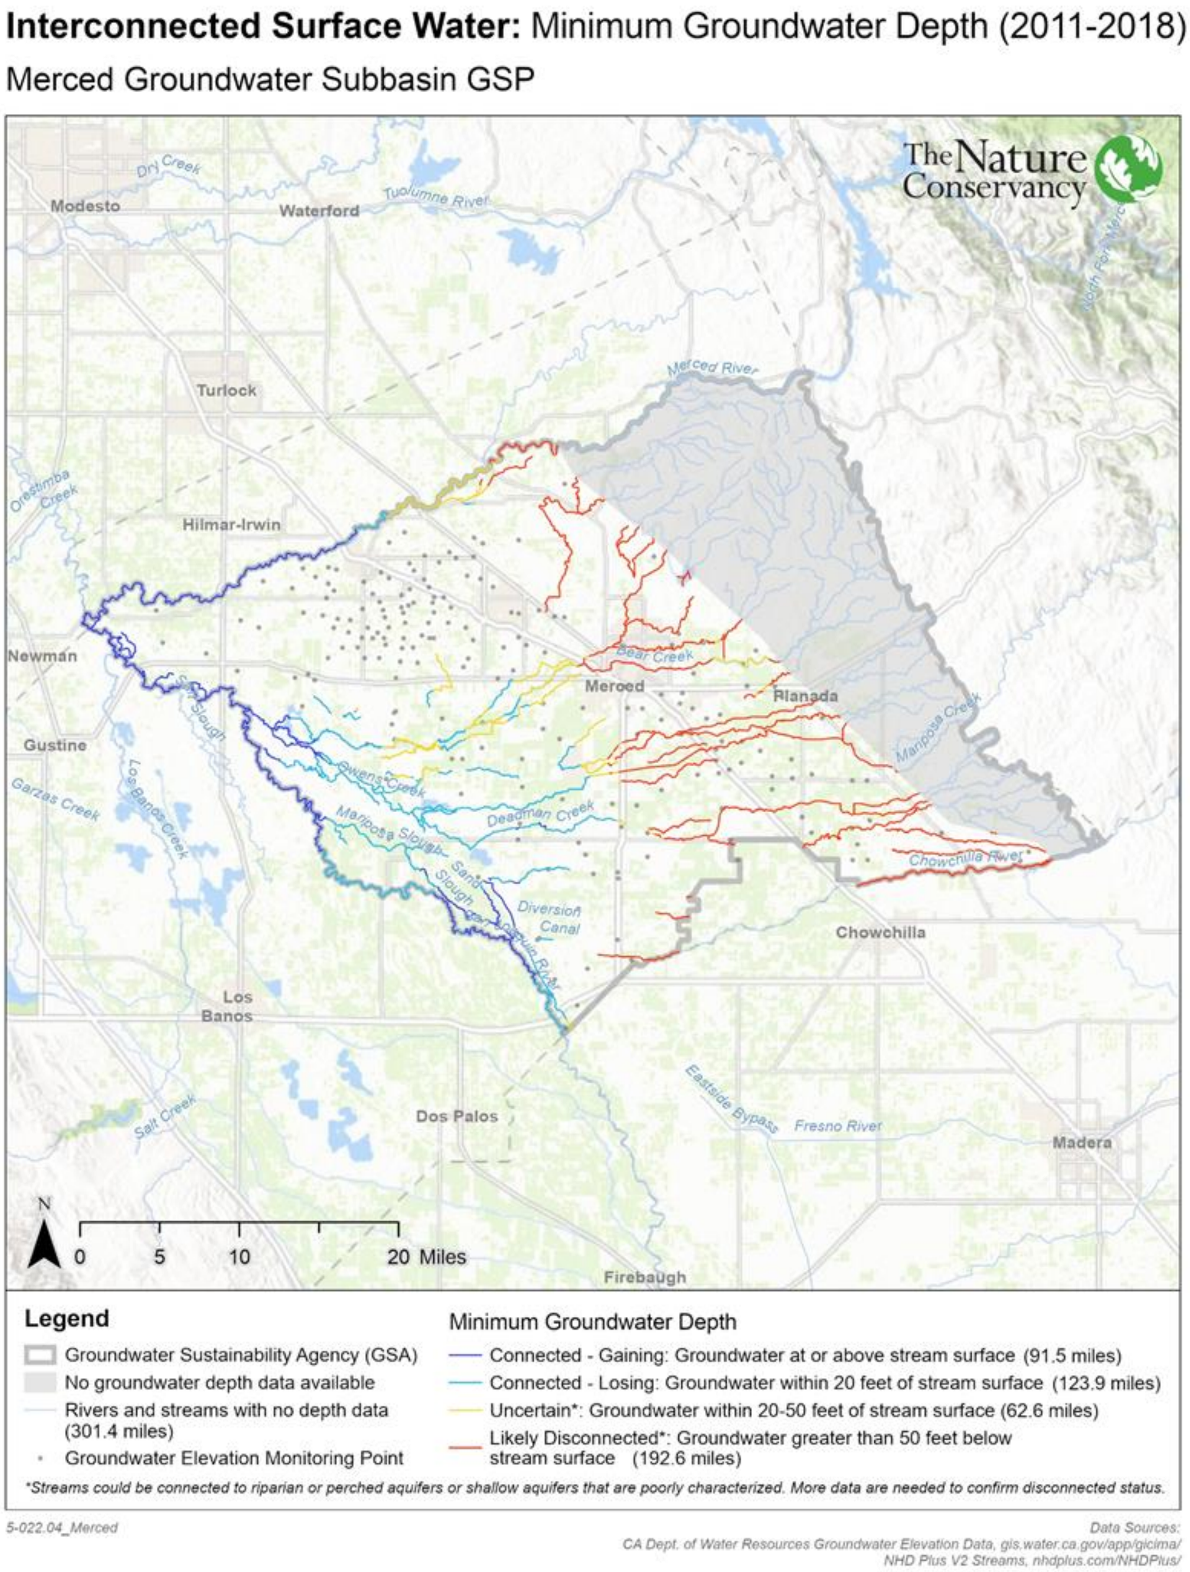
Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.



TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Mid-Kaweah Groundwater Sustainability Plan (GSP), Kaweah Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Mid-Kaweah Groundwater Sustainability Agency's (GSA's) Mid-Kaweah Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were unreasonable (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address gaps within 180 days. In these cases, we strongly recommend that the Department set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP.

<u>Our Key Considerations</u>

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as only 2 out of 38 of our comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

<u>TNC recommendation</u>: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly ignored potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were not adequately analyzed in the GSP. The GSP provides a narrative description of surface water reaches in the Kaweah subbasin, but does not attempt to specify or map interconnected reaches or estimate the quantity and timing of streamflow depletions. Therefore, potential ISWs may not be managed in the GSP.

<u>TNC recommendation</u>: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on surface water-groundwater interconnectivity and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 220 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under*

SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not adequately identify, map and consider GDEs. We believe that this does not meet plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on groundwater levels that were greater than 50 feet at a single point in time. While we appreciate the use of a more conservative groundwater depth threshold, this is a technically problematic approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unidentified and unprotected in the GSP.

TNC recommendation: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in Attachment D on best practices for utilizing the NC dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We would like to commend the GSP for including the groundwater demands of phreatophytes in the historical, current and projected water budgets. As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget. Please clarify if other categories of native vegetation and managed wetlands were included in the water budget, and include them if omitted.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and/or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to

[1] *Available at:* https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Potential GDEs are located in areas of the subbasin where no shallow groundwater monitoring currently exists or is proposed, leaving data gaps unfilled. Potential ISWs have been dismissed in the GSP, without proposed recommendations to improve ISW identification, mapping, and depletion estimates. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Mid-Kaweah Groundwater Sustainability Plan

A complete draft of the Mid-Kaweah Groundwater Sustainability Plan (GSP) was provided for public review on July 31, 2019; TNC submitted comments on the Draft GSP on September 9, 2019. Public draft GSP comments and responses, provided as Attachment D of the GSP, were reviewed and are referred to below. The GSP comments and responses are also provided in Attachment F of this letter. We reviewed the responses to comments and the text of the Final GSP (dated December 18, 2019) to determine if changes were made to the Final GSP that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, and states whether or not they were addressed in the Final GSP *[as green text within brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

- [Section 1.5.2 Beneficial Uses and Users (p. 1-23 to 1-25)]
  - *[No GSP text changes were made in response to our comment.]* Surface water users and the following groups were listed as Beneficial Users: "Environmental and ecosystem interests in MKGSA include representatives of the Tulare Basin Wildlife Partners, Sierra Club Mineral King Group, and Sequoia Riverlands Trust (p. 1-25)." **Please identify whether or not the following beneficial uses and users of groundwater in the subbasin are present: Protected Lands, including preserves, refuges, conservation areas, recreational areas; and other protected lands; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
  - *[No GSP text changes were made in response to our comment.]* The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. **To identify environmental users, please refer to the following:**
    - Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/
    - The list of freshwater species located in the Kaweah Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8).

- [Section 1.4.3 General Plans in Plan Area (p. 1-12 to 1-16)]

- *[No GSP text changes were made in response to our comment.]* This section should include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals, rather than being limited to goals and policies directly related to groundwater resources as the Tulare General Plan does. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**
- *[No GSP text changes were made in response to our comment.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin, and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**
- *[No GSP text changes were made in response to our comment.]* The Open Space and Conservation Element of the City of Visalia's General Plan includes (p. 1-14 to 1-15):

  "1. Protect, restore and enhance a continuous corridor of native riparian vegetation along Planning Area waterways, including the St. Johns River; Mill, Packwood, and Cameron Creeks; and segments of other creeks and ditches where feasible, in conformance with the Parks and Open Space diagram of this General Plan.

  2. Establish design and development standards for new projects in waterway corridors to preserve and enhance irrigation capabilities, if provided, and the natural riparian environment along these corridors. In certain locations or where conditions require it, alternative designs may be appropriate (e.g., terraced seating or a planted wall system)

  3. Place special emphasis on the protection and enhancement of the St. Johns River Corridor by establishing extensive open space land along both sides

  4. Where no urban development exists, maintain a minimum riparian habitat development setback from the discernible top of the bank: 50 feet for both sides of the Mill, Packwood, and Cameron Creek corridors and 25 feet for both sides of Modoc, Persian, and Mill Creek ditches. Where riparian trees are located within 100 feet of the discernible top of the banks of the creek corridors and 50 feet from the banks for the ditches, the setback shall be wide enough to include five feet outside the drip line of such trees. Restore and enhance the area within the setback with native vegetation as follows:

     a. Where existing development or land committed to development prohibits the 50-foot setback on Mill, Packwood, and Cameron Creek corridors, provide the maximum amount of land available for a development setback

     b. Where existing development or land committed to development prohibits the 25-foot setback along Modoc, Persian, and Mill Creek ditches, provide the maximum amount of land available for a development setback."

  Please specify if any of these areas are potential GDEs and describe how they are managed.

- *[No GSP text changes were made in response to our comment.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**

- *[No GSP text changes were made in response to our comment.]* [Appendix 2A Section 2.3.1 Existing Groundwater Level Monitoring (p. 37-38)] The monitoring programs are described, but there is no mention of how GDEs are monitored and protected. **Once GDEs are identified, please describe how existing groundwater monitoring programs are protective of GDEs, or propose additional monitoring that specifically targets GDEs.**
- *[No GSP text changes were made in response to our comment.]* [Appendix 2A Section 2.3.4 Existing Stream Flow Monitoring (p. 50)] This section describes the programs of USACOE, Kaweah and St. Johns Rivers Association (KSJRA), and the ditch companies. Surface water sources are listed along with the group monitoring them. Small surface streams which pass through TID's service area are noted as used, but the names are not listed. There is no mention of ISWs or GDEs and how they are monitored. **Please explain how existing stream flow monitoring is protective of ISWs and GDEs.**
- *[No GSP text changes were made in response to our comment.]* [Section 1.4.4 Well Permitting Process (p. 1-17)] **This section should include a discussion of the following:**
    - Future well permitting must be coordinated with the GSP to assure achievement of the Plan's sustainability goals. The County of Tulare is currently revising their well permitting program. The City of Visalia also has a well permitting program for wells within their jurisdiction.
    - The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). The need for well permitting programs to comply with this requirement should be stated in the text.

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14); The Hydrogeologic Conceptual Model should illustrate the relationship between GDEs, surface waters, and principal aquifers.

- *[No GSP text changes were made in response to our comment.]* [Appendix 2A Section 2.2.4 Bottom of the Subbasin (p. 22)] The base of the Subbasin corresponds with the base of freshwater. "This is generally defined as the elevation below which total dissolved solids are greater than 2,000 milligrams per liter (mg/l) (Bertoldi et al, 1991)" (p. 22 of Appendix 2A). As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP

[2] *The Critical Species LookBook is available at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/*

(https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.

- *[No GSP text changes were made in response to our comment.]* [Appendix 2A Section 2.2.1.3 Kaweah Subbasin Geology (p. 17-21)] Basin-wide cross sections provided in Figures 4 through 13 are regional, and do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. **Please consider including an example near-surface cross section that depicts the conceptual understanding of shallow groundwater and stream interactions at different locations, including the Upper Aquifer, as well as any potential GDEs**.

Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16); Identification of ISWs is a required element of Current and Historical Groundwater Conditions (23 CCR §354.16).

- *[No GSP text changes were made in response to our comment.]* [Appendix 2A Section 2.9 Interconnected Surface Water (p. 145)] The discussion of interconnected surface waters should first be introduced in Appendix 2A Section 2.4 (Groundwater Elevation and Flow Conditions §354.16), since the identification of interconnected surface water systems is a required element of Current and Historical Groundwater Conditions (23 CCR §354.16). In Appendix 2A Section 2.4 (Groundwater Elevation and Flow Conditions §354.16), please expand this discussion, in particular:
    - The regulations [23 CCR §351(o)] define interconnected surface waters (ISW) as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. **Please identify interconnected surface waters in the Basin by relying on groundwater elevation and stream gauge data, specifying any data gaps that exist so that they can be resolved in the monitoring network.**
    - ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface Digital Elevation Model that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. Groundwater elevations that are always deeper than 50 feet below the land surface can be used to identify the aboveground reaches as disconnected surface waters. **Please reconcile data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells) along**

surface water features in the Monitoring Network section of the GSP to improve ISW mapping.

- *[No GSP text changes were made in response to our comment.]* [Section 3.2.1.5 Interconnected Surface Water Systems (p. 3-4)] "Depletions of interconnected surface waters are minimal and, to the extent they occur, impact only vegetation along the banks of unlined channels within the forebay regions of the aquifer system where natural channels exhibit gaining reaches from time to time. Undesirable results may occur should any such groundwater-dependent vegetation disappear from locations of known historic existence." This discussion is inadequate and is not supported by data. **Please expand the discussion of ISWs to include the above referenced recommendations on identifying and mapping ISWs and provide discussion of the depletions on specific rivers or creeks.**

Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16); Identification of GDEs is a required element of Current and Historical Groundwater Conditions (23 CCR §354.16).

- *[No GSP text changes were made in response to our comment.]* [Section 5.3.5 Minimum Thresholds – Interconnected Surface Waters (p. 5-17)], [Appendix 2A Section 2.2.7.3 Delineation of recharge areas, potential recharge areas, and discharge areas, including springs, seeps, and wetlands (p. 33)], and [Appendix 2A Section 2.10 Groundwater Dependent Ecosystems (p. 146)] All three of the above referenced sections refer to or include discussion of the identification of groundwater dependent ecosystems (GDEs). **Please consolidate and expand these sections of the document in GSP Appendix 2A Section 2.4 (Groundwater Elevation and Flow Conditions §354.16), since the identification of groundwater dependent ecosystems (GDEs) is a required element of Current and Historical Groundwater Conditions (23 CCR §354.16)**. This is a more appropriate place for the identification of GDEs, since groundwater conditions (e.g., depth to groundwater, interconnected surface water maps, groundwater quality) are necessary local information and data from the GSP in assessing whether polygons in the NC dataset are connected to groundwater in a principal aquifer. For detailed guidance on how to address GDEs, please see our publication, *GDEs under SGMA: Guidance for Preparing GSPs*[3]. In particular, note the following:
    - *[No GSP text changes were made in response to our comment.]* **Please provide a comprehensive discussion and figure(s) for the identification of GDEs**. Figure 19 of Appendix 2A is titled "Potential Groundwater Dependent Ecosystems", however the figure does not actually present this. The NC dataset is a starting point for GSAs to identify GDEs in their basin. The NC dataset comprises 3,488 acres of potential GDEs for the entire Kaweah basin, representing a significant amount of GDEs to be considered. **Please map the original NC dataset on Figure 19 or another figure, and document which polygons were added (and what**

[3]GDEs under SGMA: Guidance for Preparing GSPs is available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

local sources were used to identify them), removed (and the removal reason), and kept (from the original NC dataset). The basin's GDE shapefile, which is submitted via the SGMA Portal, should also include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were added or removed).

- *[No GSP text changes were made in response to our comment.]* **Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network**. Specifically, please note:
  - *[Our comment was addressed. We thank the GSA for providing an updated map for depth to groundwater in response to the comment below, Figure 2-2 of Final GSP.]* **Please provide depth to groundwater contour maps. See Attachment D for best practices for completing this step. Specifically, ensure that the first step is contouring groundwater elevations, and the subtracting this layer from land surface elevations from a Digital Elevation Model (DEM) to estimate depth to groundwater contours across the landscape**. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make.
  - *[No GSP text changes were made in response to our comment.]* Figure 19 presents areas marked as 'Spring 2015 Groundwater Surface within 50 feet of Ground Surface'. Spring 2015 is after the SGMA benchmark date of January 1, 2015. **Please rely on groundwater condition data prior to the SGMA benchmark date**.
  - *[No GSP text changes were made in response to our comment.]* It is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2015) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to**

describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network.

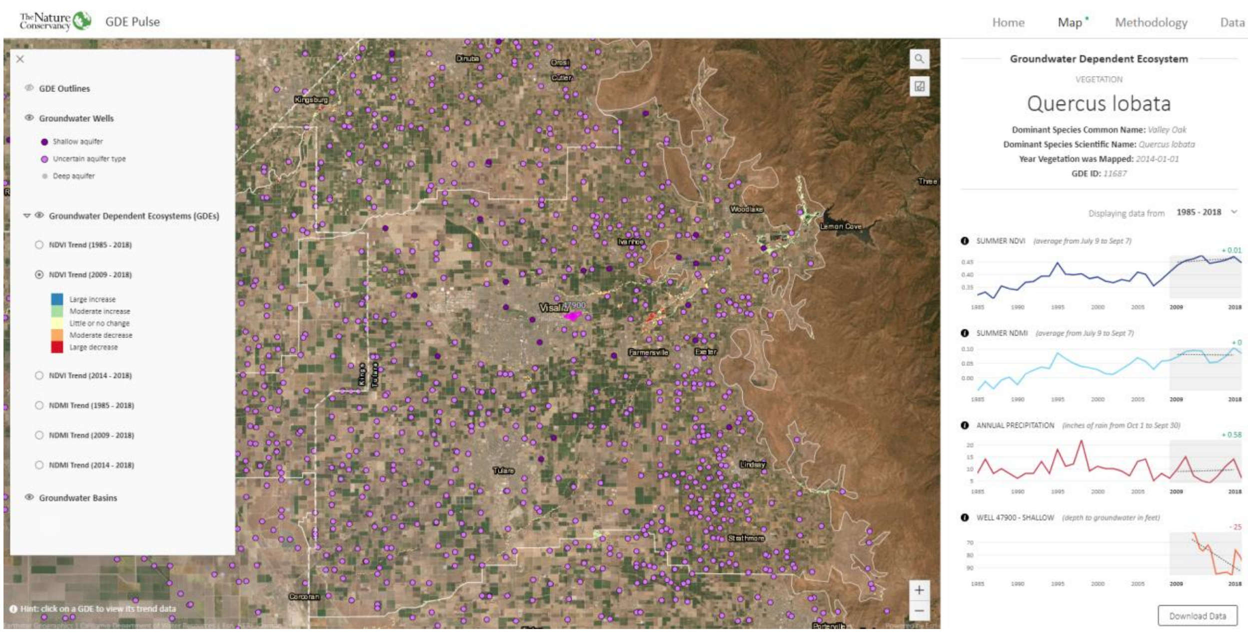
- *[No GSP text changes were made in response to our comment.]* **Please specify which data were used to determine the elevation of the stream or river bottom and the Valley Oak root zone in the basin**. Page 5-18 states "The water table lies some 60 to 150 feet below the invert of all three of these channel reaches, which is generally 40 to 130 feet below the root zone of the Valley Oak", however no information is provided on the data used to determine the elevation of the stream or river bottom and these calculations. These depths suggest a root zone of approximately 20 feet, but this is not stated explicitly. There is a citation to data (Lewis and Burgy, 1964[4]) which indicates root zones deeper than 70 feet for this species in a fractured rock aquifer. Rooting depths for the Valley Oak in this region have not been reported, and are a data gap. Furthermore, care must be taken when considering rooting depths of vegetation. Rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant. Maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not like to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths. In addition, while it is likely to be true that shallow water availability is necessary to support the recruitment of saplings, hydraulic lift of groundwater to shallow depths has been observed in Quercus spp.
- *[No GSP text changes were made in response to our comment.]* Page 33 of Appendix 2A states "The locations of these potential GDEs and hydrographs for the Subbasin indicate that the vegetation of these areas are dependent surface water flows, rather than shallow groundwater." We disagree with this statement dismissing all potential GDEs from further consideration. There are 3,488 acres of potential GDEs within the Kaweah subbasin as per the NC dataset, and the location is, as to be expected, at the interconnection between groundwater and surface water. Adverse impacts can occur to GDEs due to pumping that further separates groundwater from surface water. **Please provide the rationale for this statement, including the discussion of the type of river reach (i.e., gaining or losing)**. Riparian vegetation may still be accessing groundwater, and hence be identified as a GDE. We highly recommend that depth to groundwater levels under the NC polygons be used as the evaluation criteria, since access to groundwater could be occuring in/near losing reaches. **Please refer to Attachment D of this letter for best**

[4] *Lewis, D.C. and Burgy, R.H., 1964. The relationship between oak tree roots and groundwater in fractured rock as determined by tritium tracing. Journal of Geophysical Research, 69(12), pp.2579-2588.*

practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. Specifically, it is highly advised that fluctuations in the groundwater regime be characterized in space and time to understand the seasonal and interannual groundwater variability in GDEs.

Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)

- *[No GSP text changes were made in response to our comment.]* **Once potential GDEs are identified, please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present**. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the Mid-Kaweah Subbasin:



- *[No GSP text changes were made in response to our comment.]* Once potential GDEs are identified, provide an inventory of the vegetation types or habitat types and rank the vegetation species as having a high, moderate or low value. **Please identify whether any endangered or threatened freshwater species of animals and plants or areas with critical habitat were found in any of the GDEs**. The list of freshwater species located in the Kaweah Subbasin can be found in Attachment C of this letter.

Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)

- [Appendix 2A Section 2.5.1.3 Summary of Water Budget Components (p. 102)]
    - *[Our comment was addressed. We appreciate that phreatophyte extraction is defined in the final GSP. This element was added to the water budget, and it is noted that this is a minor component of the water budget. This is presented in Table 30 (p. 102) of Appendix 2A.]* Please clarify what the term "phreatophyte extraction' means. The text states 'Phreatophyte extraction consists of removing vegetation in riparian areas to prevent consumptive water use." If phreatophytes were indeed removed from within the Subbasin, please provide further details. If phreatophyte extraction refers to the uptake of groundwater by phreatophytes, then correct this text. It should be clearly stated if the phreatophytes are referring to GDE vegetation (riparian vegetation).
    - *[No GSP text changes were made in response to our comment.]* **Please clarify what assumptions and data were used to calculate the outflow term from groundwater by phreatophytes.**

Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)

- *[No GSP text changes were made in response to our comment.]* [Section 3.1 Sustainability Goal (p. 3-2)] "The broadly stated sustainability goal for the Kaweah Subbasin as agreed to by the three GSAs therein is, for each GSA to manage groundwater resources to preserve the quality of life through maintaining the viability of existing enterprises of the region, both agricultural and urban." There is no mention of protection of ISWs or GDEs, and no indication that environmental stakeholders were consulted. **Please expand the goal to include protection of GDEs, ISWs, and critical habitats.**
- *[No GSP text changes were made in response to our comment.]* [Section 3.2.1.5 Interconnected Surface Waters (p. 3-4)] The statement "Depletion of interconnected surface waters are minimal and, to the extent they occur, impact only vegetation along the banks of unlined channels within the forebay regions of the aquifer system…." is not backed up by evidence presented in the GSP. **Once ISWs are analyzed per our comments on Checklist Items 8, 9, and 10 above, please revise this section, noting any data gaps to be filled.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

- *[No GSP text changes were made in response to our comment.]* [Section 5.4.1 Groundwater Level Measurable Objectives (p. 5-18 to 5-20)] The measurable objective was set equal to the water level at 2030 using the 2006-2016 water level trend for each of the wells selected as representative monitoring sites. The specific measurable objectives for all of the selected wells are listed in Table 5-3. **Please explain how the measurable objectives will help achieve the sustainability goal as it pertains to the environment. After GDEs and ISWs are identified,**

please discuss if any impacts to GDEs or ISWs are expected. Data gaps should be noted and addressed in the Monitoring section.

Checklist Items 27 to 29 – Minimum Thresholds (23 CCR §354.28)

- *[No GSP text changes were made in response to our comment.]* [Section 5.3.1 Minimum Thresholds – Chronic Lowering of Groundwater Levels (p. 5-1 to 5-9)] The trend of the 2006-2016 water levels over time was used to set the minimum threshold at 2040 for each of the wells, used as representative monitoring sites, in each of four hydrogeologic zones within the Subbasin (shown on Figure 5.1, p. A5-1). The minimum thresholds and other sustainable criteria for each well are listed in Table 5-3 (p. 5-5). The minimum threshold derived in this manner means that it is based on a pre-SGMA level. **After GDEs are identified, please add discussion of the possible impacts to the environment. Data gaps should be noted and addressed in the Monitoring section.**

Checklist Items 30 to 46 – Undesirable Results (23 CCR §354.26)

- *[No GSP text changes were made in response to our comment.]* [Section 3.2.2.5 Interconnected Surface Waters (p. 3-7)] **Please specifically cite "periodic comparisons of surface water elevations and flowrate depletion in applicable stream channels and adjacent groundwater" as a data gap and further address in the monitoring section.**
- *[No GSP text changes were made in response to our comment.]* [Section 3.2.3.5 Interconnected Surface Waters (p. 3-9)] As noted above, an inventory of the vegetation types or habitat types and ranking of the vegetation species as having a high, moderate or low value will provide rational for the statement that "the intermittent nature of this vegetative habitat is such that its temporary loss does not rise to the level of an undesirable result."
- *[No GSP text changes were made in response to our comment.]* [Section 5.3.1.2 Undesirable Results (p. 5-2)] After the identification and evaluation of potential GDEs is completed, this section should discuss impacts to those GDEs. Specifically,
    - For chronic lowering of water level, the GSP Committee considered that one-third of the representative monitoring sites (wells) exceeding minimum thresholds for water levels would constitute an undesirable result. There appears to be no additional guidance to protect potential GDEs or ISWs. **Please discuss how this undesirable result can be used to avoid impacts to GDEs or ISWs.**
    - There appears to be no consideration of undesirable results on land uses that include and consider recreational uses (e.g. fishing/hunting, hiking, boating) and property interests that include and consider privately and publicly protected conservation lands and open spaces, including wildlife refuges, parks and natural preserves. **Please describe how impacts to these types of properties will be avoided.**
    - **Please provide more specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize**

a significant and unreasonable impact to GDEs. The definition of 'significant and unreasonable' is a qualitative statement that is used to describe when undesirable results would occur in the basin, such that a minimum threshold can be quantified. Potential effects on all beneficial users of groundwater in the basin need to be taken into consideration. According to the California Constitution Article X, §2, water resources in California must be "put to beneficial use to the fullest extent of which they are capable". **Please identify appropriate biological indicators that can be used to monitor potential impacts to environmental beneficial users due to groundwater conditions. Refer to Appendix E of this letter for an overview of a free, new online tool for monitoring the health of GDEs over time.**

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

- [Section 4.4 Groundwater Level Monitoring Network (p.4-6 to 4-11)]
  - *[No GSP text changes were made in response to our comment.]* The GSP proposes to use groundwater level monitoring for chronic groundwater level. Some of the monitoring wells are missing well construction information (only 22 of 37 wells are complete). Only 14 of the 37 wells are screened in the Upper Aquifer. The missing well information is a known data gap and was acknowledged on p. 4-15. Two multi-level wells are proposed to help fill this data gap, shown on Figure 4-7 (p. 4-22). **The missing information should be obtained or a different well selected for monitoring.**
  - *[No GSP text changes were made in response to our comment.]* "As stated previously, the interconnection of surface water and groundwater was disrupted many decades ago in the MKGSA. Therefore, a monitoring network and monitoring is not required for this GSA (p. 4-14)." Data has not been presented to substantiate this statement. **Please provide additional analysis to back-up this conclusion.**
  - *[No GSP text changes were made in response to our comment.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *and related surface conditions* (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of complicated factors, and this relationship is not characterized or discussed. As such, it is not possible to determine whether the proposed monitoring, minimum thresholds and measurable objectives are sufficiently protective to ensure significant and unreasonable impacts to GDEs and ISWs will be prevented. **Please add monitoring of potential GDEs and at any locations where ISWs have been or were previously present.**

- *[No GSP text changes were made in response to our comment.]* [Section 8.1 Annual Reporting Summary to DWR (p. 8-1 to 8-2)] "Groundwater contour maps submitted during the first five years may reflect a composite of the principal aquifers within the subbasin due to data gaps as discussed in Section 2 of this Plan. As additional dedicated monitoring wells are installed, and as more knowledge is gained regarding subbasin hydrogeology, groundwater conditions within each separate aquifer will be better understood (p. 8-1)." **A groundwater elevation map should be prepared for the Upper Aquifer above the Corcoran Clay**, as that is the only way one can determine the appropriate depth relationships between the surface water and the groundwater, which are needed to designate a GDE. Mixing shallow and deep wells, particularly when confined conditions may be present, can be misleading.

Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

- [Section 7 Projects and Management Actions (p. 7-1)] A summary of projects and management actions are listed on p. 7-1 and described in the following pages (p. 7-2 through 7-30).
  - *[No GSP text changes were made in response to our comment.]* Most of the proposed projects involve recharge to groundwater. "Visalia Eastside Regional Park & Groundwater Recharge project to be built by the City of Visalia consists of a 250-acre park featuring diverse recreational opportunities, native plants, wildlife habitat, and integrated groundwater replacement and storm water retention facilities (p. 7-26)." This is an example of a project with environmental benefits and multiple other benefits. Consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please state how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
  - *[No GSP text changes were made in response to our comment.]* Recharge ponds, reservoirs and facilities for managed stormwater recharge can be designed to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such facilities have been incorporated into local HCPs, more fully recognizing the value of the habitat that they provide and the species they support. For projects that will be constructing recharge ponds, **please identify if there will be habitat value incorporated into the design and how the recharge ponds will be managed to benefit environmental users.**

Attachment C

Freshwater Species Located in the Kaweah Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Kaweah Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[5]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[6] as well as on The Nature Conservancy's science website[7].

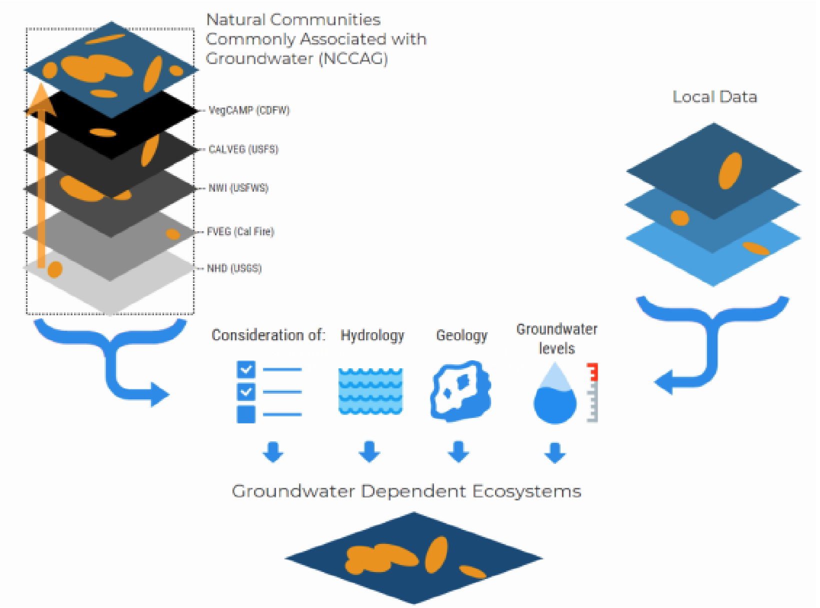
IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[8] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[9]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48

[8] *NC Dataset Online Viewer:* *https://gis.water.ca.gov/app/NCDatasetViewer/*

[9] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[10]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[11] on the Groundwater Resource Hub[12], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

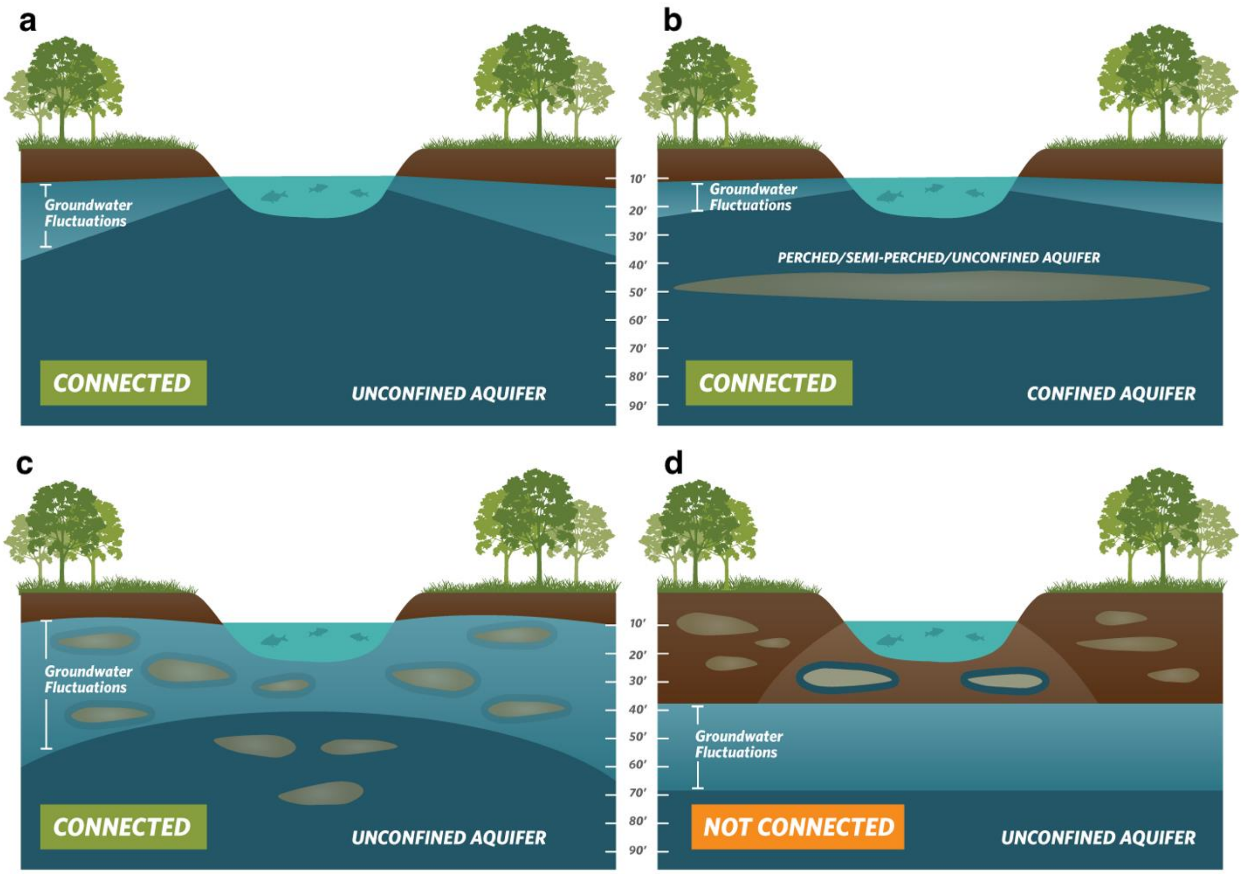

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[13] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[14] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[15] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[16]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

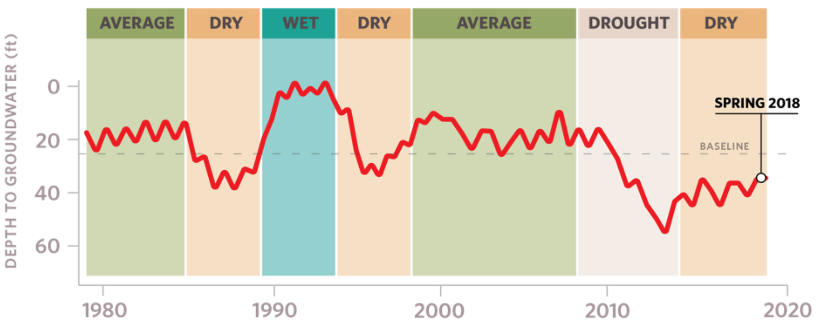

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

---

[13] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[14] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[15] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[16] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[17], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

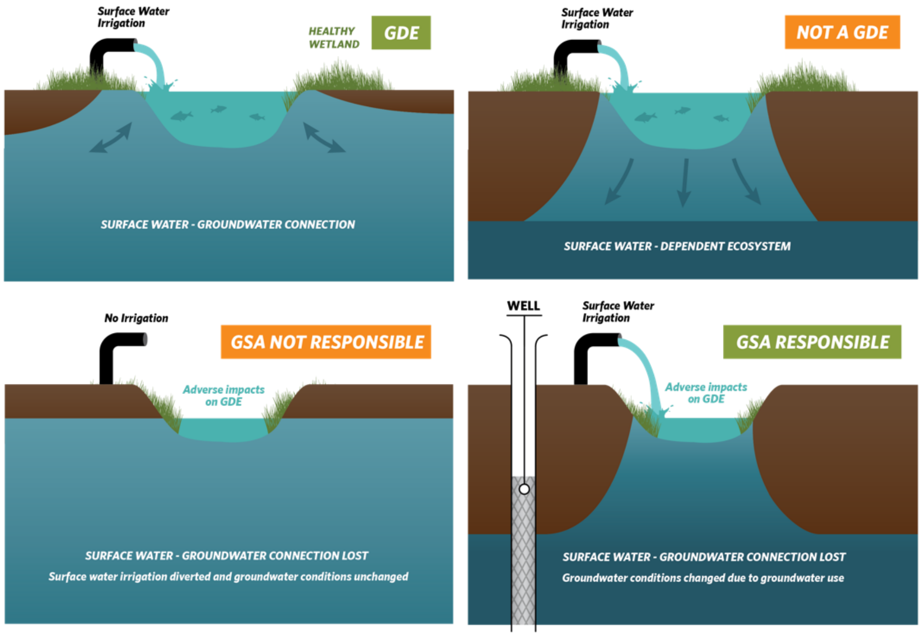

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[17] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

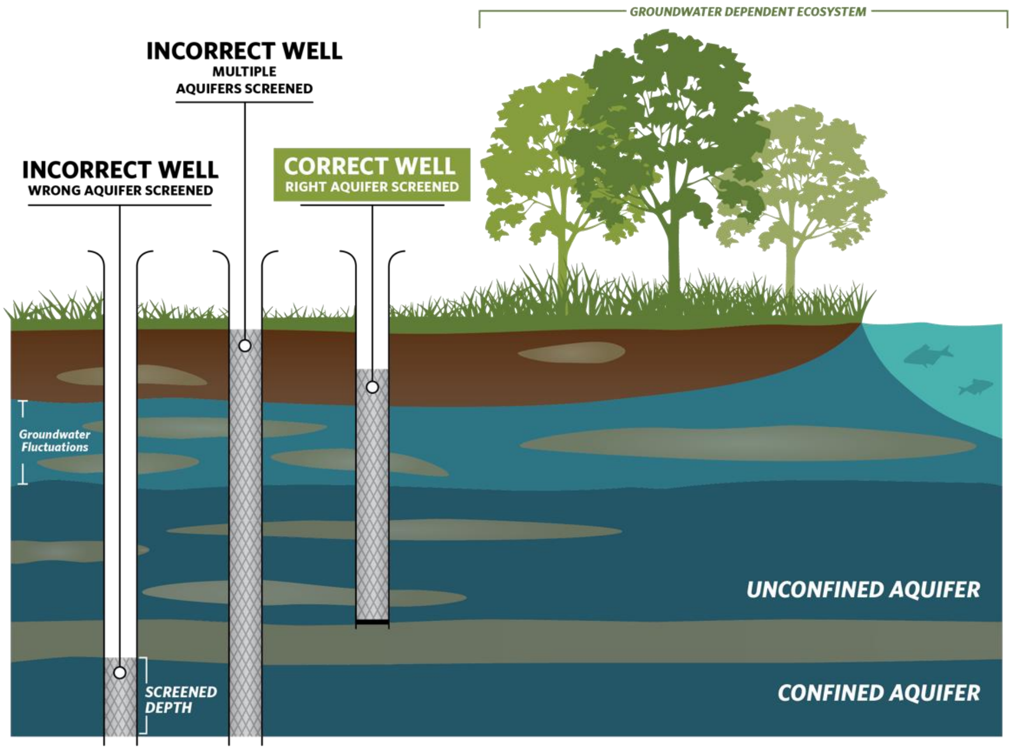

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[18] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

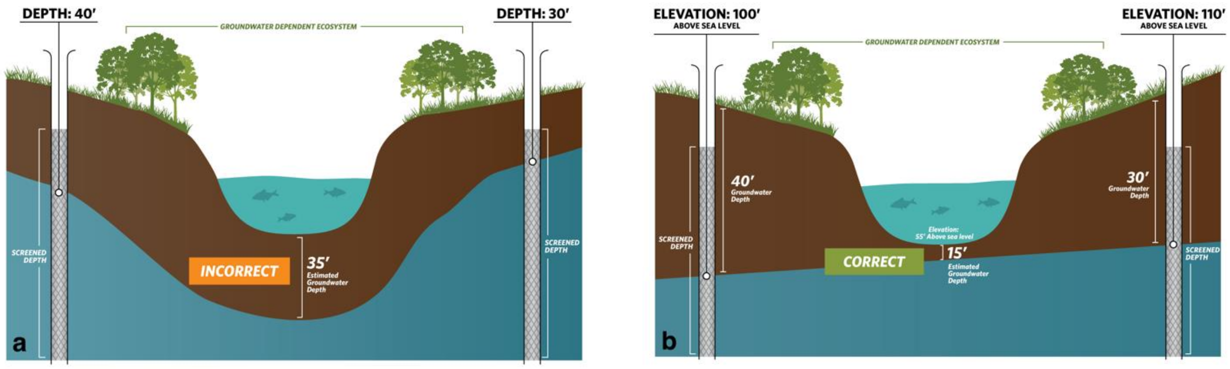

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

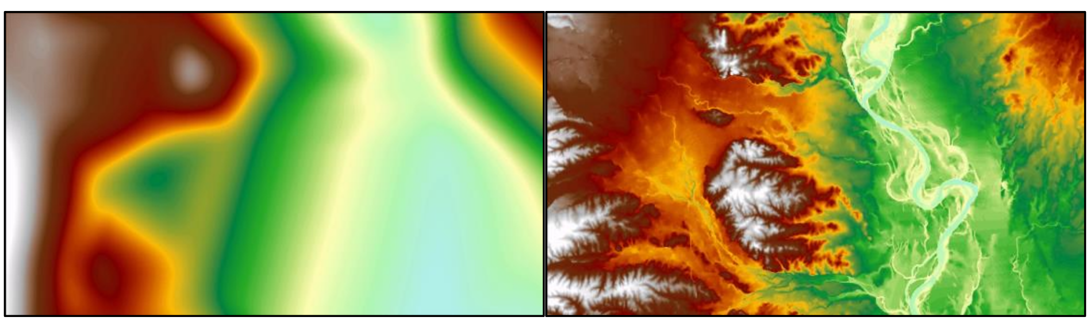

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[18] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

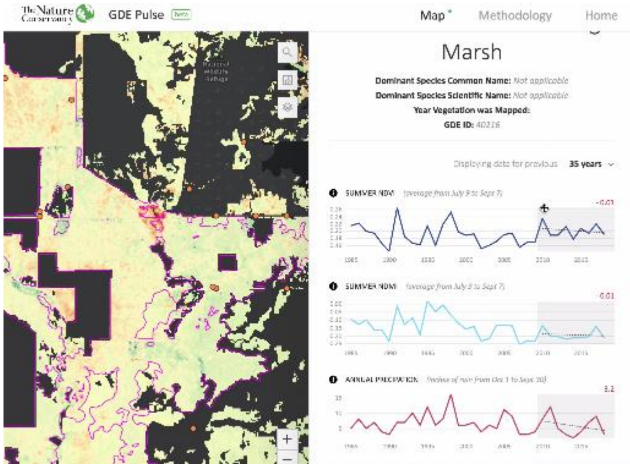
Attachment E

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[19]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[20]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Attachment F

The GSA Response to TNC Comments on Draft GSP can be found on DWR's SGMA portal as Part 2 of 2 of TNC's comments on the Final GSP.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[21]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[22]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[23] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: North Fork Kings Groundwater Sustainability Plan (GSP), Kings Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the North Fork Kings Groundwater Sustainability Agency's (GSA's) North Fork Kings Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of potential ISWs.

<u>Our Key Considerations</u>

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been largely ignored in the final plan, as only 5 out of 60 of our comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

<u>TNC recommendation</u>: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were excluded based on lack of continuous saturation between surface water and groundwater. This justification of automatic removal is incorrect and inconsistent with the definition of ISWs. The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. Therefore, potential ISWs are not being managed in the GSP.

<u>Map and Assessment of potential ISWs</u>:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the North Fork Kings GSP, 11.9 miles have uncertain connection to groundwater. Attachment G contains a one-page method summary and a GSP-specific map of ISWs in the basin. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on surface water-groundwater interconnectivity and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 1,842 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not adequately identify, map and consider GDEs. We believe that this does not meet plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on the following:

- GDEs were rejected on the basis that groundwater levels were greater than 30-ft at a single point in time. This is a technically incorrect approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30-ft or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unprotected in the GSP.
- The presence or proximity of surface water, which does not necessarily prove that the plants and animals do not access groundwater. GDEs can simultaneously rely on multiple sources of water (i.e., both groundwater and surface water), or shift their reliance on different sources on an interannual or inter-seasonal basis.

TNC recommendation: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in Attachment D which provides best practices for using the NC dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We would like to commend the GSP for including the groundwater demands of riparian vegetation in the historical, current and projected water budgets.

[1] *Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf*

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Potential GDEs are located along surface water bodies where no further shallow groundwater monitoring is proposed, leaving recognized data gaps unfilled. Potential ISWs have been dismissed in the GSP, without proposed recommendations to improve ISW identification, mapping, and estimates of depletions. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

Attachment A

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
North Fork Kings Groundwater Sustainability Plan
Comments based on Draft and Final GSP Drafts

The North Fork Kings Groundwater Sustainability Plan (NFKGSP) adopted December 18, 2019 was reviewed by TNC. Public draft GSP comments and responses, provided as Appendix 2B of the GSP, were reviewed and are referred to below. The TNC comments and responses are also provided in Attachment F of this letter. This attachment lists our original comments on the complete public draft GSP as submitted to the GSA during the public comment period, and states whether or not they were addressed in the final GSP [as green text in brackets]. The original comments were re-worded where necessary as noted below. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 2.5.1 Description of Beneficial Uses and Users (pp. 2-39 to 2-40)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* The beneficial uses and users of groundwater focused on agricultural users, municipal users, disadvantaged communities, and agencies conducting groundwater monitoring, but environmental groups were not listed. **Please describe how environmental groups were engaged during the GSP development process.**
- *[Minor changes to the GSP text do not adequately address our comment.]* The Kings River Fisheries Management Program is described in Section 2.2.2 Limits to Operational Flexibility. This program includes year-round flows, improved temperature control, and monitoring requirements. The SJRRP also increases flows to benefit fisheries. The benefits and requirements of these programs should be discussed here. **Please discuss whether other beneficial uses and users of groundwater in the NFKGSA area are present: Protected Lands, including preserves, refuges, conservation areas, recreational areas and other protected lands; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
- *[Our comment was not identified in Appendix 2B; no changes to GSP text made.]* The types and locations of environmental uses, species and habitats supported, instream flow requirements, and other designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the NFKGSA area should be specified. **To identify environmental uses and users, please refer to the following:**
  - The NC Dataset (https://gis.water.ca.gov/app/NCDatasetViewer/) which identifies potential presence of groundwater dependent ecosystems in this basin
  - The list of freshwater species located in the Kings Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.

- CDFW's California Natural Diversity Database (CNDDB) (https://www.wildlife.ca.gov/Data/CNDDB)
- USFWS's IPAC report for the North Fork Kings Area of the Subbasin (https://ecos.fws.gov/ipac/)

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8)

[Section 2.2.1 Monitoring and Management Programs (p. 2-17 to 2-22)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* [Groundwater Level Monitoring (p. 2-17)] The Kings River Conservation District (KRCD) began studying groundwater level trends in 1987 and prepared annual groundwater reports between 2003 and 2014 that included regional groundwater contour maps. In 2005, they developed the Lower Kings Groundwater Management Program (under SB 1938), which includes the North Fork Kings GSA (NFKGSA) area as Management Area B. The KRCD program may cease when a SGMA-approved groundwater monitoring program is implemented for the Kings Subbasin. KRCD serves as the designated monitoring entity under CASGEM for western Fresno and Kings Counties. **Please describe how existing groundwater monitoring programs are protective of GDEs and ISWs or propose additional monitoring that specifically targets GDEs.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* [Groundwater Extraction Monitoring (p. 2-19)] The GSP notes that while municipal water agency wells are metered and the extracted volume is known, most private wells are not metered, so the volume extracted is not known. The text states that "The vast majority of groundwater pumping within the NFKGSA is not currently metered" (p. 2-19). This omission means that the groundwater used must be estimated using factors such as water use per capita and crop water demand per acre. This estimation contributes to the uncertainty of the water budget. **Please describe how this data gap will be filled in the future.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* [Surface Water Monitoring (p. 2-22)] This section briefly describes the types of monitoring by the Kings River Water Authority (KRWA). There is no mention of ISWs or GDEs and how they are monitored. **Please explain the relationship of existing stream flow monitoring to the protection of ISWs and GDEs, and if there are instream flow criteria for the ISWs.**

[Section 2.2.2 Impacts to Operational Flexibility (p. 2-22 to 2-25)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* The Kings River Fisheries Management Program includes year-round flows, improved temperature control, and monitoring requirements. This section should discuss or reference any instream flow requirements, especially flow needs for critical species and their habitats, including the amount, time of year when the flow minimum is specified, the duration, the species for which it applies, associated permits that set forth the requirements, and the regulating agency setting forth the compliance requirements. The Kings River Flood Control District also has built levees along the portion of the Kings River shown in Figure 2-9 (p. 2-24) that are maintained by KRCD with assistance from the United States Army corps of Engineers (USACE). **Please discuss the potential impact of the Kings River Fisheries Management Program on the aquatic species and habitat present along the river.**

[Section 2.3 Relation to General Plans (p. 2-27 to 2-28)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* The General Plans for Fresno County and Kings County apply within the NFKGSA area. Both were completed prior to the development of the GSA. This section should be modified to include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.**
- *[The GSA's response states that there are no HCPs or NCCPs in NFKGSA. For clarity please add this to GSP text.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the NFKGSA area and if they are associated with critical habitat, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the NFKGSA area and address how GSP implementation will coordinate with the goals of HCPs or NCCPs.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**

[Section 2.3.4 Permitting New or Replacement Wells (p. 2-29)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* **Please include a discussion of how future well permitting will be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* The State Third Appellate District recently found that counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF vs. SWRCB and Siskiyou County, No. C083239). **Compliance of well permitting programs with this requirement should be stated in the GSP.**

[Section 2.4.4 Well Abandonment/Well Destruction (p. 2-34)]

[2] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

- *[Our comment was adequately addressed through GSP text changes. Thank you for acknowledging the environmental importance of proper well abandonment and that proper characterization of each individual aquifer zone is necessary for protection of beneficial users of groundwater.]* The counties of Fresno and Kings have the authority to require permits for well abandonment/well destruction, but due to staffing and funding limitations the GSP notes that enforcement of this requirement is limited. **Please describe what actions will be taken by NFKGSA to make sure that wells are properly abandoned.** The GSP also states that well owners will be encouraged to convert the wells into monitoring wells. **Please include text to clarify that only wells screened in one aquifer and thus appropriate for monitoring will be included in the monitoring program.**

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 3.1.7 Cross-sections (p. 3-15)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* Regional basin-wide cross sections provided in Figures 3-9, 3-12, and 3-13 include the NFKGSA area. These cross-sections do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. The cross-sections have been taken from a 1969 source and, as reproduced in the GSP, are very difficult to read and understand. **Please reproduce the regional cross-sections so that they can be understood by the reader and update them to illustrate data obtained from more recent well installations. Please clearly state whether localized perched aquifers are present in the basin. Include example near-surface cross sections that depict the conceptual understanding of shallow groundwater and river interactions at different locations, including perched and regional aquifers, as well as any potential GDEs and ISWs**.

[Section 3.1.8.1 Geologic Formations (pp. 3-23 to 3-24)]

- *[Our comment has been adequately addressed through GSP text changes. Thank you for acknowledging that proper characterization of the unconfined aquifer zone is necessary for protection of environmental beneficial users of groundwater.]* The first aquitard is the extensive iron-silica hardpan layer of the Riverbank Formation, which is important in identifying where groundwater recharge can occur. The A and C clays are present in the western part of the NFKGSA area, as depicted on Figure 3-17 (p. 3-27). The E-clay, commonly known as the Corcoran Clay, is present in most of the NFKGSA area and confined conditions exist below the Corcoran Clay. In the past, it was assumed that only one aquifer existed in the eastern part where the E-clay is absent. However, this assumption is being reevaluated. KDSA has described in Appendix 3A how locally extensive clay layers can function as an aquitard, forming a confined aquifer below. This evaluation will continue and the GSP states later in Section 5 that the confined aquifer may be monitored separately in the future. **It is**

important to confirm that only wells with screened intervals in the unconfined aquifer are being used to compare with surface water to identify and confirm potential GDEs.

[Section 3.1.8.2 Aquifer Characteristics and Properties (p. 3-29)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* In the NFKGSA area, the base of the usable aquifer corresponds with the base of freshwater, defined in the text as groundwater with total dissolved solids (TDS) of 2,000 milligrams per liter (mg/l) (KDSA, 2010), consistent with other GSAs in the Subbasin. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.

[Section 3.1.12 Recharge and Discharge Areas (pp. 3-39 to 3-43]

- *[The name of the wetlands inventory was corrected but no other changes to the GSP text were made. Our original comment below has been re-worded to capture this change.]* Wetland including freshwater emergent wetlands and forest shrub wetlands were mapped along the Kings river, as shown on Figure 3-26 (p. 3-45), as identified from US Fish and Wildlife's National Wetland Inventory (NWI). "Some of the areas shown indicate perched shallow groundwater conditions caused by a restrictive clay layer" (p. 3-43). **Please clarify which clay layer is being referred to in this sentence. In this section, please refer to the discussion of GDEs in Section 3.2.8 and mapped on Figure 3-52. The NWI does not always include or segregate separate existing wetlands that are on the periphery of other features. Please describe the wetland types in more detail. If they are truly vernal pools confined by a clay layer then they are not GDEs, but they must meet the criteria of a vernal pool as described by the California Rapid Assessment Methodology or the USACE to qualify.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* The text discusses recharge basins, including wastewater effluent ponds, stormwater basins, and dedicated recharge basins, but these are not shown on Figure 3-21 (p. 3-37). **Please indicate whether the recharge basins are or could be operated as habitat suitable for migrating birds or other species and could be included in an HCP or NCCP.**

[Section 3.2.1 Groundwater Level Data (pp. 3-46 to 3-55)]

- *[The GSP text was updated to refer to a map of locations where the vertical gradients have been measured, therefore this part of our original comment was removed. No other GSP text changes were made.]* The NFKGSP notes that "The dramatic lowering of hydraulic heads in the confined parts of the aquifer has resulted in a large net downward movement of water through bore holes. This vertical flow occurs in both pumped and un-pumped wells during the growing season" (Faunt, CC ed. 2009) (p. 3-53). There is insufficient data to show groundwater elevation contours for the confined aquifer in the NFKGSA. **Please expand this section to include a discussion of the impacts of vertical flow on ISWs and GDEs.**

<u>Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)</u>

[Section 3.2.7 Surface Water and Groundwater Interconnection (pp. 3-95 to 3-96)]

- *[Neither the GSA's response nor changes made to GSP text adequately addresses our comment.]* **Please provide depth to groundwater contour maps. See Attachment D for best practices for completing this step. Specifically, ensure that the first step is contouring groundwater elevations, and the subtracting this layer from land surface elevations from a digital elevation model (DEM) to estimate depth to groundwater contours across the landscape**. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make.
- *[Our comment was not identified in Appendix 2B; no changes to the GSP text were made.]* ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface DEM that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. **Please evaluate with depth to groundwater contour maps as described above and see Attachment D for best practices to complete this step.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. The NFKGSP places emphasis on whether the flow in a given reach is continuous or not. In contrast, data are given for five reaches of the Kings River where flow was present between 14 and 39 percent of the time in the last 10 years. The GSP concludes: "There is no data currently to suggest any interconnected surface waters in the NFKGSA" (p. 3-96), however this statement has not been proven by evidence presented in the GSP No data were included to show the relationship between the depth to groundwater and the riverbed, therefore the presence of ISWs cannot be ruled out. **Please provide further evidence and analysis for the determination of whether ISWs exist in the NFKGSA area**. **As stated above, please include depth to groundwater maps utilizing a DEM of the land surface. Provide a cross-section and / or corresponding hydrographs to**

show the relationship between the river channel and the depth to groundwater at wells near the river.

Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)

[Section 2.4.11 Impacts on Groundwater Dependent Ecosystems (pp. 2-36 to 2-37) and Section 3.2.8 Groundwater Dependent Ecosystems (pp. 3-96 to 3-97)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* The NC dataset is a starting point for GSAs to identify GDEs in their basin / subbasin. The NC dataset comprises 1,842 acres of potential GDEs mapped within the NFKGSA area, representing a significant amount of GDEs to be considered. **Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled by the monitoring network.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* Figure 3-53 presents Spring 2017 depth to groundwater contours overlain on NC Dataset polygons. **Please provide more details on how the depth to groundwater contours were developed by confirming**:
  - that wells monitoring the upper unconfined aquifer are being used to verify whether polygons in the NC dataset are supported by groundwater;
  - the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons reflect local conditions relevant to ecosystems;
  - the wells used for interpolating depth to groundwater are screened within the surficial unconfined aquifer and capable of measuring the true water table; and
  - depth to groundwater is contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to create the contour maps.
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* It is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2017) can misrepresent groundwater levels required by GDEs, and inadvertently result in

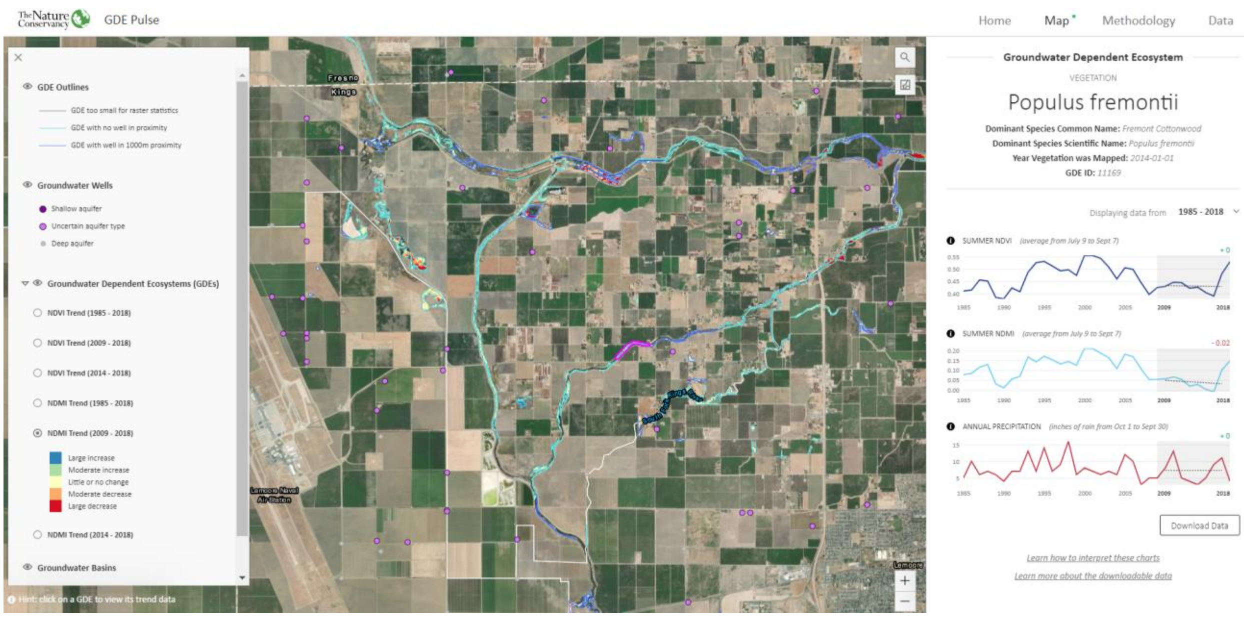
adverse impacts to the GDEs. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Ensure that groundwater condition data prior to the SGMA benchmark date of January 1, 2015 is included in the analysis. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, we strongly advise the inclusion of those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network to avoid adverse impacts.**

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* **Please provide rationale for the 30-foot criteria cited in the text.** The text states (p. 3-96): "Recognizing that much of the Kings Subbasin has a depth to groundwater greater than the deepest vegetative GDE rooting depth of thirty feet, many of the GDEs identified in the NC Dataset Viewer were mischaracterized." **In TNC's GDE Guidance, the depth criterion of 30 feet is presented as a criterion for *inclusion*, not a standalone criterion for *exclusion*.** In other words, if groundwater is within 30 feet of the ground surface, then a GDE can be identified. If it is not, then further analysis must be conducted (see Appendix III of the GDE Guidance). **The <u>actual</u> rooting depth of vegetation growing in the area should be considered, and this will vary by species dominance and habitats present. Please indicate what vegetation is present in the possible GDEs and the estimated maximum rooting depths for those species.** Many phreatophytes can and will root deeper than 30 feet but are commonly constrained by the saturated zone at and below the ground water table. As groundwater declines or rises, roots redistribute over the water table in the unsaturated zone. This may happen on a seasonal and annual basis. Furthermore, rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant. Maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not prefer to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths.
- *[Our comment was not identified in Appendix 2B; no changes to the GSP text were made.]* The text states (p. 3-97): "[V]egetation and wetlands identified by the Nature Conservancy are thought to be dependent on the surface flows in the river rather than on groundwater," although the GSP acknowledges that a shallow groundwater monitoring program is proposed to verify the conditions. **Please ensure that if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, those polygons are included in the GSP <u>until</u> data gaps are reconciled in the monitoring network.**

<u>Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)</u>

[Section 3.2.8 Groundwater Dependent Ecosystems (p. 3-96)]

- *[The GSA’s response does not adequately address our comment and no changes to the GSP text were made.]* **Please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present.** Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data (e.g., leaf area index, evapotranspiration or other data) to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the NFKGSA area.



- *[The GSA’s response does not adequately address our comment and no changes to the GSP text were made.]* **Please provide an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes the vegetation types or habitat types and rank the GDEs as having a high, moderate or low value; and what characterizes the rank.**
- *[The GSA’s response does not adequately address our comment and no changes to the GSP text were made.]* **Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found in or near any of the GDEs since some organisms rely on uplands and wetlands during different stages of their lifecycle.** Resources for this include the list of freshwater species located in the Kings Subbasin that can be found in Attachment C of this letter, the Critical Species Lookbook, and CDFW’s CNDDB database.
- *[The GSA’s response does not adequately address our comment and no changes to the GSP text were made.]* **For each identifiable GDE unit with supporting hydrological datasets please include the following:**
    - Plot and provide hydrological datasets for each GDE.

    - Define the baseline period in the hydrologic data.
    - Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater.
    - Explore cause-and-effect relationships between groundwater changes and GDEs.
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* **For each identifiable GDE unit without supporting hydrological datasets please describe data gaps and / or insufficiencies. Where there is incomplete, uncertain or conflicting data, we strongly advise that the potential GDE be recognized to avoid adverse impacts.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* **Compile and synthesize biological data for each GDE unit by including:**
    - Biological datasets for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.
    - Describe data gaps and insufficiencies.
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* **Provide a description of the potential effects on GDEs, land uses, and property interests, including:**
    - Cause-and-effect relationships between GDE and groundwater conditions.
    - Potential impacts to GDEs that are considered to be "significant and unreasonable".
    - Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters, critical habitat constraints, etc.) for significant impacts to relevant species or ecological communities.
    - Land uses that and consider recreational uses (e.g., fishing/hunting, hiking, boating, etc.).
    - Property interests, such as privately and publicly protected conservation lands and opens spaces, wildlife refuges, parks, and natural preserves.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 3.3.6 Outflows from Groundwater System (p. 3-115)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* **Please clarify whether a term is included for native or riparian vegetation evapotranspiration and for wetlands in the North Fork Kings historical, current, and future water budgets.**
- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* "During the 1997-2011 period, average annual unconfined groundwater outflows from North Fork Kings Subbasin were estimated to be 3,200 acre-feet (AF) and confined groundwater outflow was estimated to be 13,000 AF. The unconfined aquifer outflow went to McMullin Area GSA, and the confined outflows went to the adjacent Westside Subbasin" (p. 3-118). These two values were added to obtain the estimate for average annual total groundwater outflow of 16,200 AF. **Please describe how this estimate was made, given the limited number of wells installed in the confined system below the Corcoran Clay.**

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* The Friant Water Authority estimated climate change impacts on the San Joaquin River using the Water Storage Investment Program (WSIP) data sets. Given the uncertainty associated with Kings River water supply into the future, the assumption was made that the historical water delivery from the Kings River would be maintained. This assumption is highly uncertain and is not conservative. The diversion of Kings River flows may require additional provision for storage in the non-irrigation or low-irrigation season. **Please add discussion of the potential impacts to the flow in the Kings River and to groundwater conditions on GDEs, aquatic ecosystems and instream flow requirements due to climate change.**

<u>Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)</u>

[Section 4.1 Sustainability Goal (p. 4-1)] The Sustainability Goal does not consider GDEs or ISWs.

- *[Neither the GSA's response nor changes made to GSP text adequately addresses our comment.]* **Since GDEs are likely present in the NFKGSA area (please see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included.**
- *[Neither the GSA's response nor changes made to GSP text adequately addresses our comment.]* The Plan states that there are time periods of ISW connectivity along the Kings River; however, they are dismissed because they are not continuously connected. **TNC notes evidence of connectivity between surface water and groundwater and potential GDEs have been identified near the Kings River. We disagree with the statement that there are not ISWs within the GSA. Even though the ISWs are not continuously connected (see comments under Checklist Items 8-10), they are still connected at some point in time on either a longitudinal and / or lateral profile, and they should be included in the Sustainability Goal.**
- *[Neither the GSA's response nor changes made to GSP text adequately addresses our comment.]* GDEs are dependent, in part, on suitable water quality; however, the Plan only considers water quality for irrigation and domestic use. **TNC recommends including ISWs and their potential GDEs in the sustainability goal and criteria. Since GDEs may be affected by degradation of water quality, they should be included in the Sustainability Goal.**
- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* Figure 4-1 represents Path A as shown in the DWR Sustainable Management Criteria BMP (Figure 15, Potential Paths to Sustainability). This is a problematic concept however, since the Subbasin is already designated as being critically overdrafted, despite that the NFKGSA area is not yet experiencing undesirable results. This approach may slow recovery of adjacent areas or have unintended consequences that contribute to undesirable results within

the NFKGSA area and adjacent areas. **Please elaborate on how this approach to sustainability will affect the ability of adjacent GSP areas within the Subbasin to recover, and how potential unintended consequences with the NFKGSA area and adjacent areas will be evaluated.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Sections 4.2.3 Measurable Objectives for Groundwater Levels (p. 4-15)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* This Measurable Objective does not consider GDEs. GDEs are often adjacent to streams or associated with riparian corridors where ISWs exist, even if only seasonally or discontinuously along a longitudinal or lateral profile. **Please include GDEs (see comments under Checklist Items 16-20) in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.3 Measurable Objectives for Water Quality (p. 4-35)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* This Measurable Objective does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.7.2 Measurable Objectives for Interconnected Surface Water and Groundwater (p. 4-46)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* This Measurable Objective does not consider ISWs. The Plan states that there are time periods of ISWs along the Kings River; however, they are dismissed because they are not continuously connected. Even though the ISWs are not continuously connected they should be included in the Measurable Objectives. **Please include ISWs (see comments under checklist items 8-10) in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment. The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial users of surface water that could be affected by groundwater withdrawals, including environmental. Please include instream flow requirements in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28)

[Sections 4.2.2 Minimum Thresholds for Groundwater Levels (p. 4-7)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* This Minimum Threshold does not consider GDEs. **Please include GDEs in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.2 Minimum Thresholds for Water Quality (p. 4-32)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* This Minimum Threshold does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.7 Minimum Thresholds for Interconnected Surface Water and Groundwater (p. 4-46)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* This Minimum Threshold does not consider GDEs. **Please include GDEs in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**
- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* The Plan states that there are time periods of ISWs along the Kings River (p. 3-95); however, they are dismissed because they are not continuously connected. ISWs that are not continuously connected spatially and/or temporally are still ISWs and should not be excluded from this GSP. **Even though the ISWs are not continuously connected, they are still ISWs, and should be included in the Measurable Objectives.**
- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial uses and users of surface water that could be affected by groundwater withdrawals, including environmental users. **Please include any instream flow and critical habitat requirements for the Kings River in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

<u>Checklist Item 30-36 – Undesirable Results (23 CCR §354.26</u>)

[Section 4.2.1 Undesirable Results (for groundwater levels) (p. 4-3)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses that could be adversely affected by chronic groundwater level decline. **Please add**

"potential adverse impacts to GDEs" and native freshwater species to the list of potential undesirable results presented in Section 4.2.

- *[Our comment was not identified in Appendix 2B; no changes to GSP text were made.]* The GDE Pulse web application developed by TNC provides easy access to 35 years of satellite data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within and near the GSA. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture along the Kings River. An example screen shot from the GDE Pulse tool is presented under Checklist Items 11-15 above.

[Section 4.5.1 Undesirable Results (for groundwater quality) (p. 4-28)]

- *[Text was added to the GSP that further discussed and referenced the citation in our below comment. Thank you for recognizing the negative environmental consequences of overpumping and dewatering of aquitards.]* This section only describes undesirable results in terms of meeting drinking water standards. The following is a link to a paper by Smith, Knight and Fendorf (2018) titled "Overpumping leads to California groundwater arsenic threat": (https://www.nature.com/articles/s41467-018-04475-3). **The section should be modified to state that overpumping and dewatering of aquitards has been identified as a potential source of elevated arsenic concentrations above drinking water standards in San Joaquin Valley aquifers. In addition, any potential undesirable results that may impact GDEs and freshwater species should be discussed in this section.**

[Sections 4.7.1 Undesirable Results (for Interconnected Surface Water and Groundwater) (p 4-46)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* This section does not consider Undesirable Results for ISWs. The Plan states that there are time periods of ISWs along the Kings River; however, they are dismissed because they are not continuously connected. **Even though the ISWs are not continuously connected they should be included in the Undesirable Results.** The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial users of surface water that could be affected by groundwater withdrawals, including environmental. Please include instream flow requirements and critical habitat designations for the Kings River in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

[Section 5.2 Groundwater Levels (pp. 5-3 to 5-15)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* **Please address how the requirement to link and correlate groundwater level declines to biological responses, and significant**

and adverse impacts to GDEs and ISWs will be addressed by the monitoring network.

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* The proposed wells to be used for monitoring groundwater levels in the unconfined aquifer and confined aquifers are shown in Figure 5-1 (p. 5-4). Areas with spatial data gaps have been identified and are shown on the map. Many of the monitoring wells are missing well construction information, which was acknowledged as a known data gap on p. 5-10. **To accurately characterize GDEs, please clarify how the unconfined aquifer will be monitored and how many wells will be used.**
- *[Our comment was not identified in Appendix 2B; no changes to the GSP text were made.]* The Kings Subbasin has requested DWR grant funds to install cluster wells that are screened in multiple units. **Please explain how the data from these new wells will be used.**

[Section 5.7 Depletion of Interconnected Surface Water (pp. 5-36 to 5-41)]

- *[Neither the GSA's response nor changes made to the GSP text adequately addresses our comment.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater *and related surface conditions* (emphasis added). Groundwater level monitoring alone may be insufficient to establish a linkage between groundwater extraction and potentially resulting impacts to environmental resources associated with GDEs and ISWs. The cause-effect relationship between groundwater levels and the biological responses that could result in significant and unreasonable impacts to ISWs and GDEs depends on a number of complicated factors, and this relationship is not characterized or discussed. As such, it is not possible to determine whether the proposed monitoring is sufficiently protective to ensure significant and unreasonable impacts to GDEs and ISWs will be prevented. **Please offer more specific recommendations for reconciling data gaps in monitoring for ISWs. Include recommendations for shallow monitoring wells, stream gauges, and nested/clustered wells along surface water features to improve ISW mapping and inform an adequate analysis. Please discuss how the data will be used to verify possible GDEs and reaches that include ISWs.**

Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)

[Section 6.1 Introduction (p. 6-2)]

- *[The phrase 'multiple benefits' was added to the GSP text. Thank you for noting the importance of recognizing multiple benefits. No other GSP text changes were made.]* The NFKGSA area includes many GDEs and ISWs (see our comments under checklist items 8-10 and 16-20 above) that are beneficial uses and users of groundwater and may include potentially sensitive resources and protected lands. Environmental resource protection needs should be considered in establishing project priorities. In addition, consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**

[Section 6.2 Projects for Water Supply Augmentation (pp. 6-3 to 6-52)]

- *[The GSA's response does not adequately address our comment and no changes to the GSP text were made.]* This Section identifies many important projects; however, the descriptions of Measurable Objectives for these projects only identifies benefits to water level and storage. Since maintenance or recovery of groundwater levels, or construction of recharge facilities, may have potential environmental benefits in many cases i**t would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.**
  - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
  - If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting ISWs.**
  - Recharge ponds, reservoirs and facilities for managed stormwater recharge can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such multiple-benefit projects and facilities have been incorporated into local HCPs and NCCPs, more fully recognizing the value of the habitat that they provide and the species they support. For projects that construct recharge ponds, **please consider identifying if there is habitat value incorporated into the design and how the recharge ponds will be managed to benefit environmental users.**
  - For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

[Section 6.3 Management Actions (p. 6-52)]

- *[Management Action EO-3 (Water Level Impacts to Beneficial Uses and Users) was added to the GSP. Thank you for recognizing the importance of outreach to stakeholders including environmental groups during plan implementation to consider the interests of all beneficial uses and users of groundwater.]* This section discusses the Management Actions for GSP implementation and SGMA compliance; however, these actions are focused on meeting groundwater level and storage measures and do not include support for GDEs or ISWs. **Please consider modifying the Management Actions to include education and outreach for protection of GDEs and ISWs. Please update Sections 6.3.1.2 (p. 6-53) and 6.3.6.2 (p. 6-80) to include GDEs and ISWs, as well as specific management of these ecosystems and the species they provide for.**

Attachment C

Freshwater Species Located in the Kings Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Kings Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[4] as well as on TNC's science website[5].

Scientific Name	Common Name	Legally Protected Species		
		Federal	State	Other
Birds				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	BCC	SCC	BSSC - First priority
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anas strepera	Gadwall			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron			
Aythya affinis	Lesser Scaup			
Aythya americana	Redhead		SCC	BSSC - Third priority
Aythya collaris	Ring-necked Duck			
Aythya marila	Greater Scaup			
Aythya valisineria	Canvasback		SCC

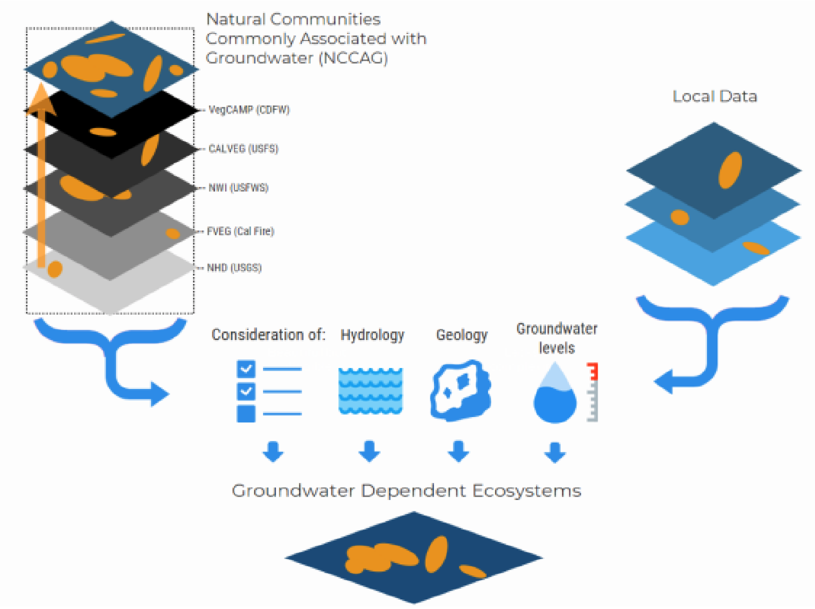
IDENTIFYING GDEs UNDER SGMA

Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[6] *NC Dataset Online Viewer:* *https://gis.water.ca.gov/app/NCDatasetViewer/*

[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

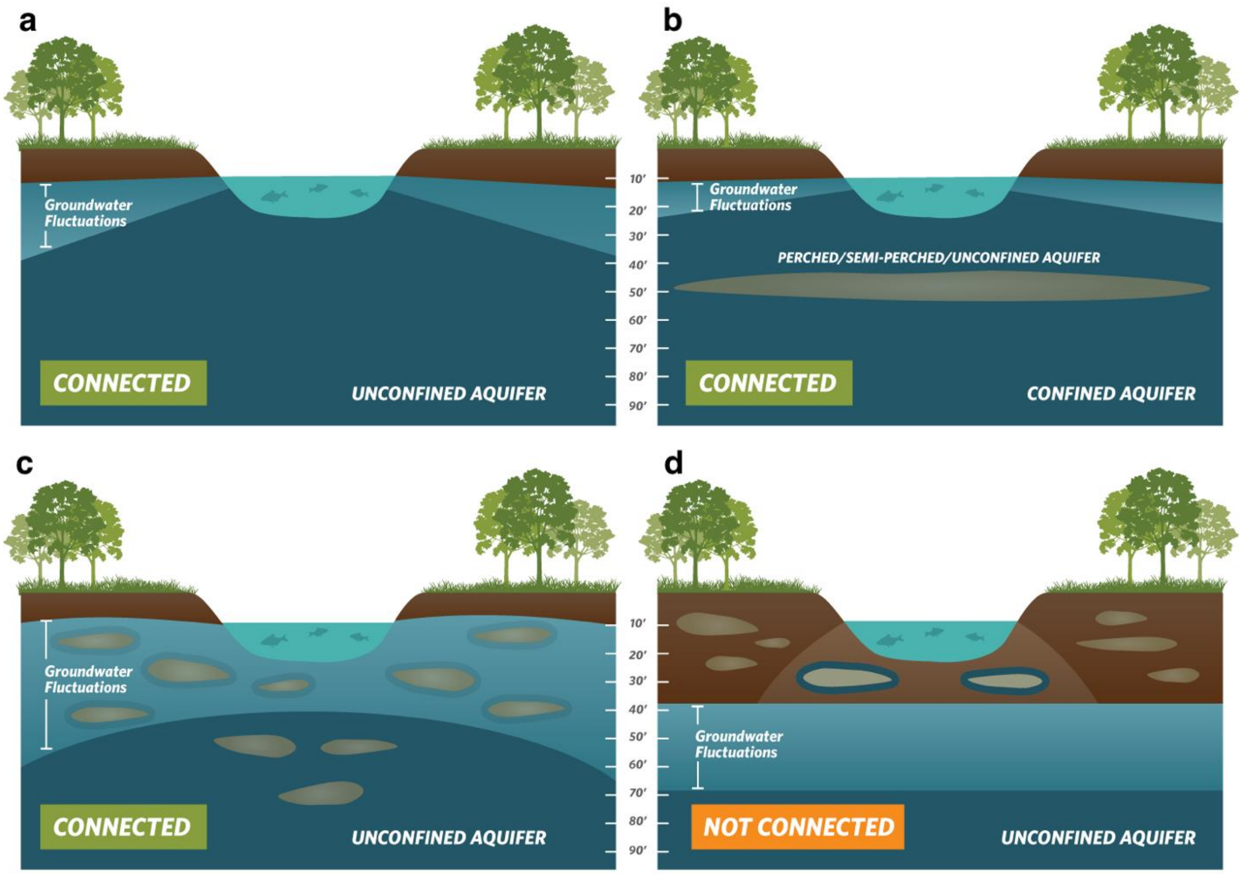

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

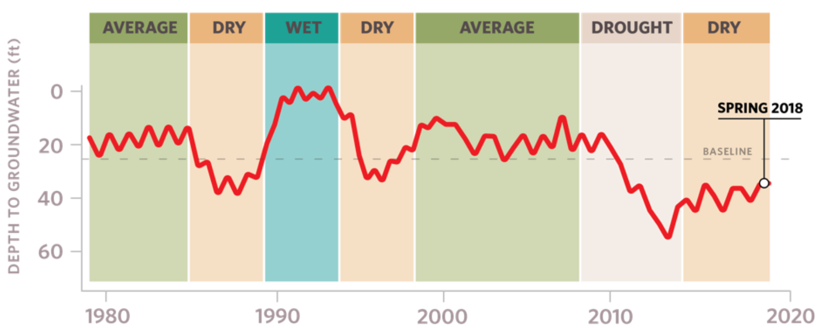

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[11] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

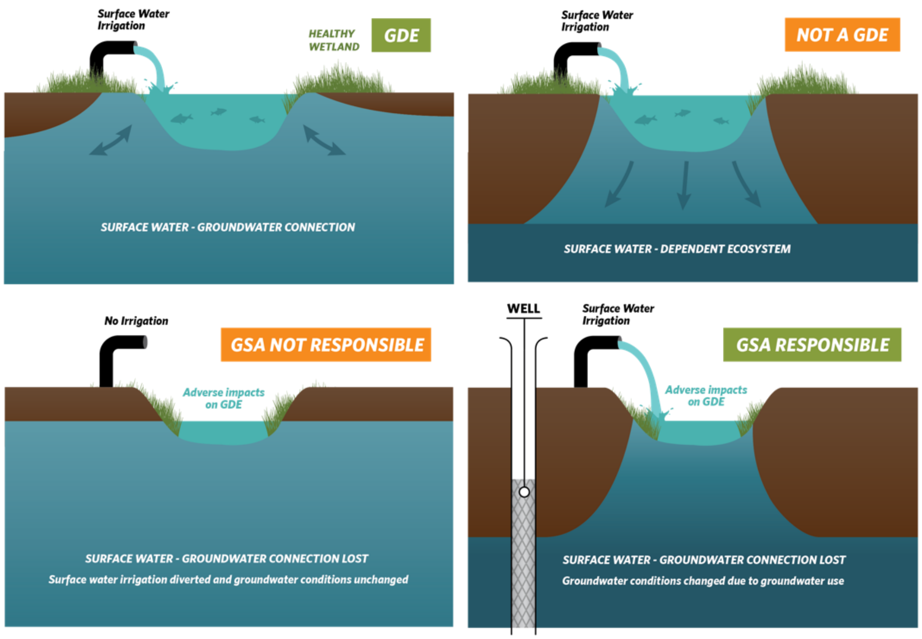

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

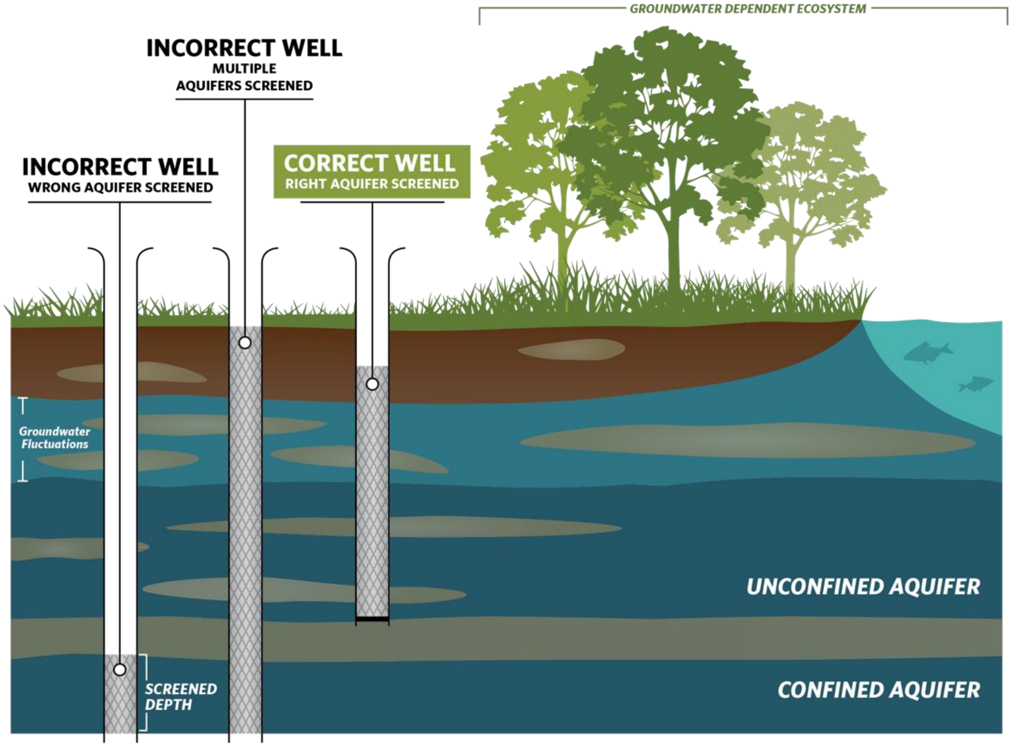

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

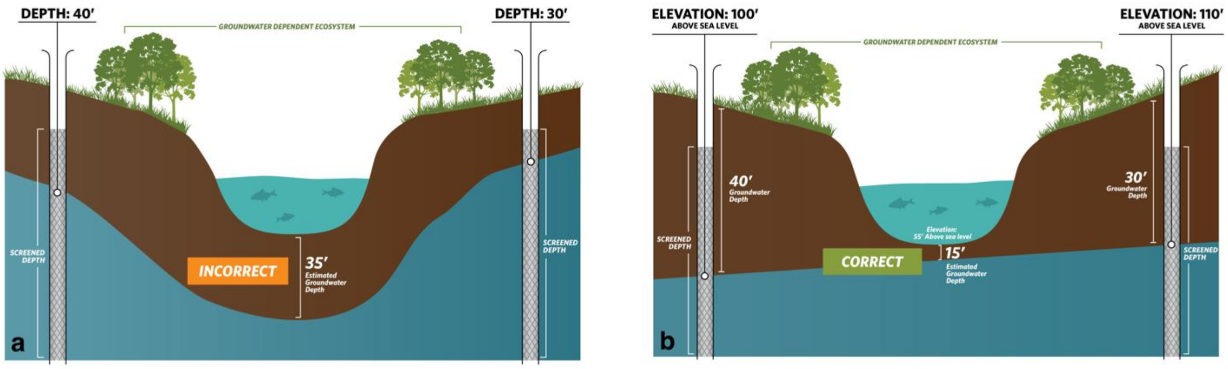

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

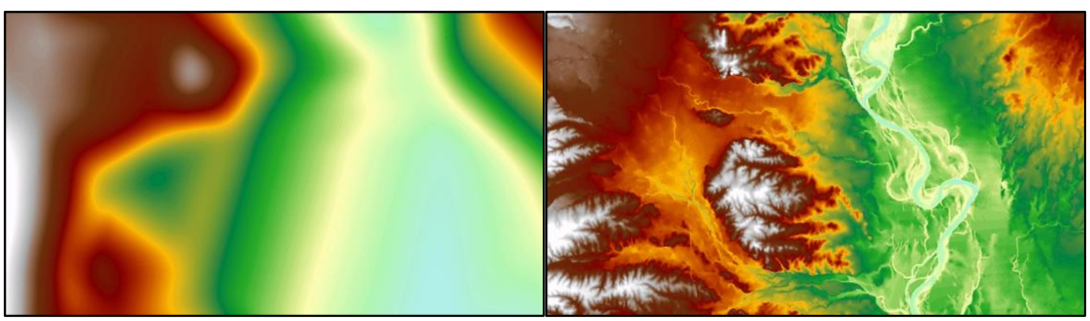

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[16] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

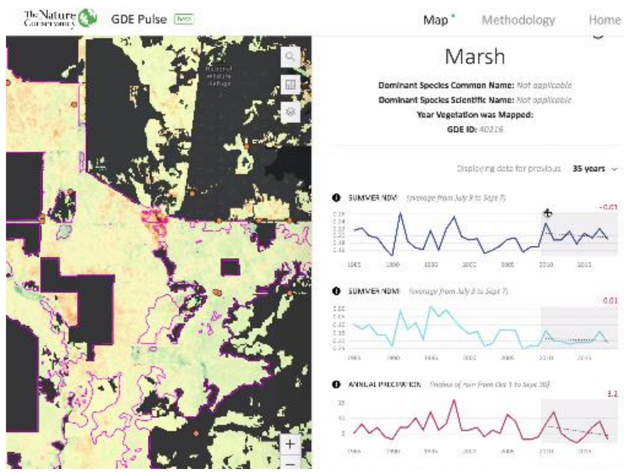
GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit
https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Attachment G

Mapping Likely Interconnected Surface Water

The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, these water features are called ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:

The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

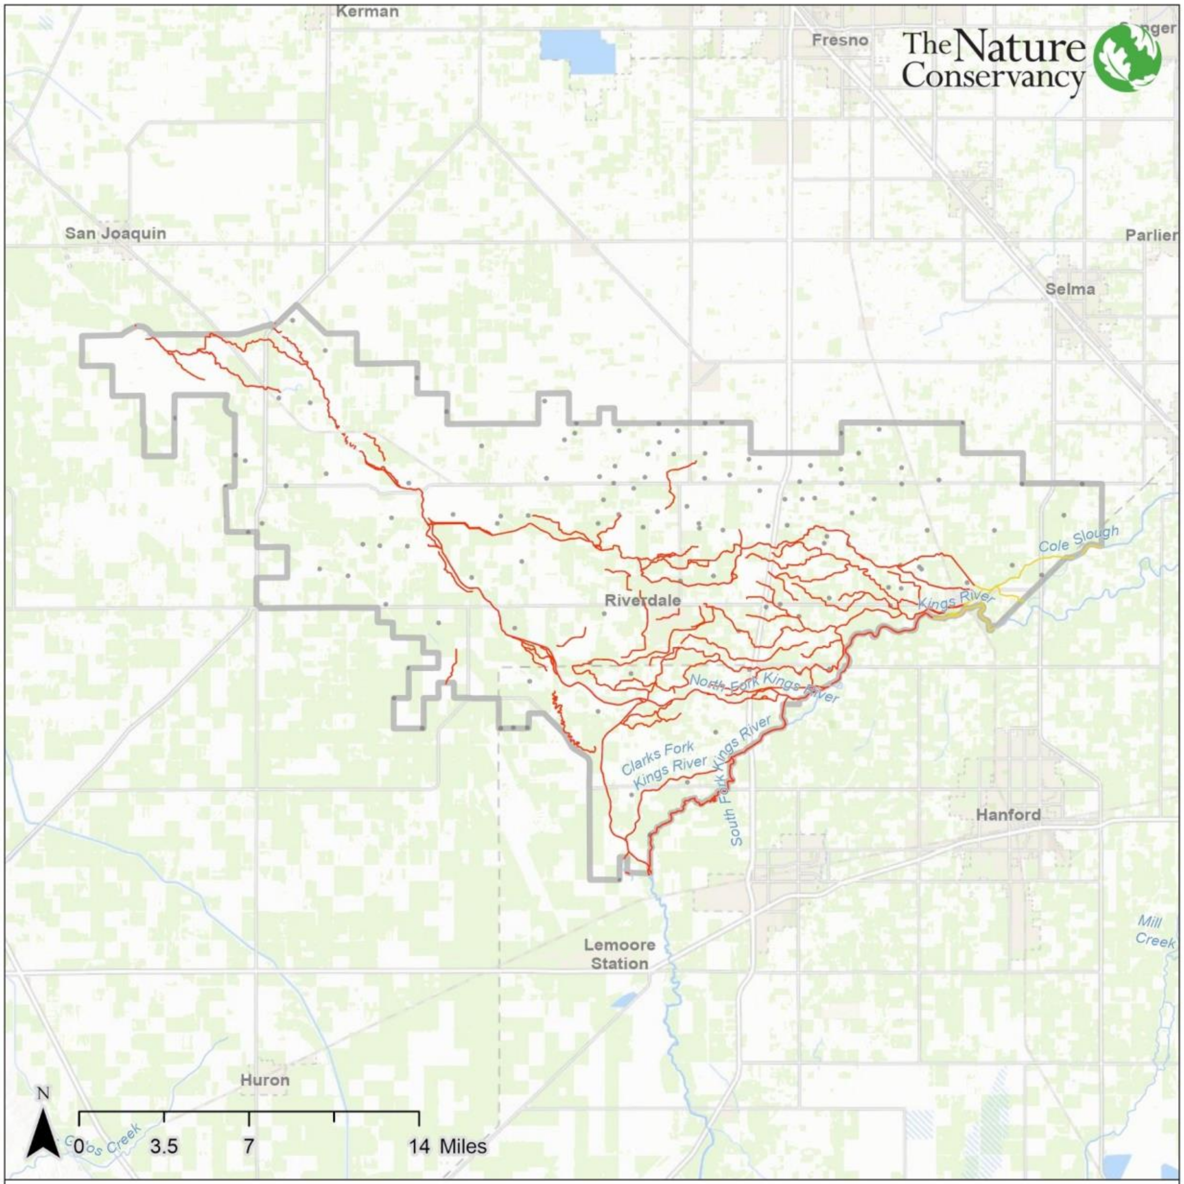
The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2011-2018)

North Fork Kings GSA GSP



Legend

- Groundwater Sustainability Agency (GSA)
- No groundwater depth data available
- Rivers and streams with no depth data (0 miles)
- Groundwater Elevation Monitoring Point

Minimum Groundwater Depth

- Connected - Gaining: Groundwater at or above stream surface (0 miles)
- Connected - Losing: Groundwater within 20 feet of stream surface (0 miles)
- Uncertain*: Groundwater within 20-50 feet of stream surface (11.9 miles)
- Likely Disconnected*: Groundwater greater than 50 feet below stream surface (227.6 miles)

Streams could be connected to riparian or perched aquifers or shallow aquifers that are poorly characterized. More data are needed to confirm disconnected status.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: North Kings Groundwater Sustainability Plan (GSP), Kings Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the North Kings Groundwater Sustainability Agency's (GSA's) North Kings Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing sustainable groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides the GSA's response to TNC's comments on the Draft GSP. Attachment G provides a map and method summary of potential ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as only 1 out of 57 of our comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

TNC recommendation: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). ISWs were incorrectly excluded based on automatically characterizing losing streams as disconnected. This justification for removal was not substantiated with further data or analysis. The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. Our analysis of groundwater levels from 2011 to 2018 indicate extensive areas of ISW in the GSP, including most of the San Joaquin River along the northern border of the GSA and other smaller stream west of Fresno (see Attachment G). Therefore, potential ISWs are not being managed in the GSP.

Map and Assessment of potential ISWs:
By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the North Kings GSP, 22.8 river miles are gaining, 31.9 are losing, and the rest are uncertain or likely disconnected (based on streams with available groundwater depth data). Attachment G contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the

minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

TNC recommendation: Until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. We recommend that the GSA conduct a thorough analysis of existing data on surface water-groundwater interconnectivity and estimate the quantity and timing of streamflow depletions in the subbasin. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 1,959 acres of potential GDEs occur in the GSA boundary. TNC developed the *Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs*[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not adequately identify, map and consider GDEs. We believe that this does not meet plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on groundwater levels that were greater than 30-feet at a single point in time. This is a technically incorrect approach since groundwater levels fluctuate over seasonal and interannual time scales due to California's Mediterranean climate and intensifying flood and drought events due to climate change. Justifying the removal of NC dataset polygons solely based on this criterion does not acknowledge that groundwater levels temporally vary and the fact that many plant species within GDEs can access groundwater depths beyond 30-ft or have adapted water stress strategies to deal with intermittent periods of deep groundwater levels. Using this methodology disregards groundwater fluctuations and can leave many GDEs unprotected in the GSP.

TNC recommendation: TNC recommends that the GSA utilize groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in Attachment D which provides best practices for using the NC dataset to identify and consider GDEs throughout the GSP. Specifically, the GSA should use a Digital Elevation Model (DEM) when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). The GSP only focused on a subset of water use sectors, including urban and agricultural users of groundwater. This is problematic because key environmental uses of groundwater are not being accounted for as water supply

[1] *Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf*

decisions are made using this budget nor will they likely be considered in project and management actions.

TNC recommendation: As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

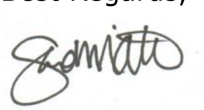
TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater. Potential GDEs are located along surface water bodies where no further shallow groundwater monitoring is proposed, leaving recognized data gaps unfilled. Potential ISWs have been dismissed in the GSP, without proposed recommendations to improve ISW identification, mapping, and estimates of depletions. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but sustainable groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,



Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

TNC Evaluation of the
North Kings Groundwater Sustainability Plan
Comments based on Draft and Final GSPs

The North Kings Groundwater Sustainability Plan (NKGSP) adopted November 21, 2019 was reviewed by TNC. Public draft GSP comments and responses, provided as Appendix 2E of the GSP, were reviewed and are referred to below. The TNC comments and responses are also provided in Attachment F of this letter. This attachment lists our original comments on the complete public draft GSP as submitted to the GSA during the public comment period, and states whether or not they were addressed in the final GSP [as green text in brackets]. Comments are provided in the order of the checklist items included as Attachment A.

<u>Checklist Item 1 - Notice & Communication (23 CCR §354.10)</u>

[Section 2.5.1 Description of Beneficial Uses and Users (p. 2-35)]

- *[The GSA's response of "Thank you for your comments. All comments are given due consideration" does not address our comment and no changes to GSP text were made.]* Environmental and Ecosystem Interests were listed as Beneficial Users of groundwater. Surface water users were also listed as Beneficial Users, as long as there is hydrologic connection between surface water and groundwater bodies. No further description of the environmental or ecosystem interests or surface water users was given. The Kings River Fisheries Program and the San Joaquin River Restoration Program (SJRRP) are described in Section 2.2.2 (Impacts to Operational Flexibility). The Kings River program includes year-round flows, improved temperature control, and monitoring requirements. The SJRRP program also increases flows to benefit fisheries. The benefits and requirements of these programs should be discussed here. **Please describe whether other beneficial uses and users of groundwater in the NKGSA area are present, including protected Lands, preserves, refuges, conservation areas, recreational areas; managed wildlife areas, and other protected lands; and Public Trust Uses, including wildlife, aquatic habitat, fisheries, and recreation.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the NKGSA area should be specified. **To identify environmental uses and users, please refer to the following:**
  - Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/
  - The list of freshwater species located in the Kings Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.
  - CDFW's CNDDB - https://www.wildlife.ca.gov/Data/CNDDB
  - USFWS's IPAC report for the NKGSA area -https://ecos.fws.gov/ipac/

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8)

[Section 2.2.1 Monitoring and Management Programs (pp. 2-16 to 2-17)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* Groundwater Level Monitoring (p. 2-16) programs have been implemented by the Fresno Irrigation District since 1920. They collect data from other irrigation districts and agencies and prepared annual reports. Most of the agencies within the North Kings GSP were formerly part of the Fresno Area Regional Groundwater Management Group. The Kings River Conservation District (KRCD) also collects water level data in the NKGSA area. **Please describe how existing groundwater monitoring programs are protective of GDEs or propose additional monitoring that specifically targets GDEs.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* The Surface Water Monitoring section (p. 2-17) briefly describes the types of monitoring by the Fresno Irrigation District, Kings River Water Association (KRWA), the Friant Water Authority, the cities of Fresno and Clovis, and other water districts. There is no mention of ISWs or GDEs and how they are monitored. **Please explain the relationship of existing stream flow monitoring to the protection of ISWs and GDEs.**

[Section 2.2.2 Impacts to Operational Flexibility (pp. 2-18 to 2-23)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The SJRRP requires the release of flows from Friant Dam to the confluence with the Merced River to support the life-stages of salmon and other fish. These restoration flows will allow more groundwater seepage when the system is fully operational, which is estimated to be after 2029. Table 2-3 (p. 2-22) lists potential impacts in reduced water deliveries from the San Joaquin River. This section should discuss or reference any instream flow requirements, especially flow needs for critical species, including the amount, time of year when the flow minimum is specified, the duration, the species for which it applies, associated permits that set forth the requirements, and the regulating agency setting forth the compliance requirements. **Please discuss the potential impact of the SJRRP on the aquatic species and habitat present along the river and within adjacent habitats supported by the river.**

[Section 2.3 Relation to General Plans (pp. 2-24 to 2-28)]

- *[The GSA's response does not address our comment. Minor changes to GSP text do not adequately address our comment.]* There are three city general plans (Fresno, Clovis, and Kerman) and the Fresno County General Plan within the NKGSA area. All were completed prior to the development of the GSA. The plans should be modified to include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and**

procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the NKGSA area and if they are associated with critical habitat, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the NKGSA area and address how GSP implementation will coordinate with the goals of HCPs or NCCPs.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical habitat for these aquatic species and their relationship to the GSP.**

[Section 2.3.4 Permitting New or Replacement Wells (p. 2-27 to 2-28)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Please include a discussion of how future well permitting will be coordinated with the GSP to ensure achievement of the Plan's sustainability goals.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* The State Third Appellate District recently found that counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). **The need for well permitting programs to comply with this requirement should be stated in the text.**

[Section 2.4.4 Well Abandonment/Well Destruction Program (p. 2-32)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The County of Fresno has the authority to require permits for well abandonment and/or well destruction, but due to staffing and funding limitations the GSP notes that enforcement of this requirement is limited. The Cities of Clovis and Fresno also require that wells be properly destroyed within their city limits. **Please describe what actions will be taken by the NKGSA to make sure that wells are properly abandoned.** The GSP also states that well owners will be encouraged to convert the wells into monitoring wells. **Please include text to clarify that only wells screened in one aquifer and are appropriate for monitoring will be included in the monitoring program.**

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 3.1.7 Cross-sections (p. 3-14)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* Basinwide cross sections provided in Figures 3-7 through 3-12 (pp. 3-15

[2] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

through 3-20) are regional, and do not include a graphical representation of the manner in which shallow groundwater may interact with ISWs or GDEs that would allow the reader to understand this topic. The cross-sections have been taken from a 1969 source and as reproduced in the GSP, are very difficult to read and understand. **Please reproduce the regional cross-sections so that they can be understood by the reader and update them to illustrate data obtained from more recent well installations. Include an example near-surface cross section that depicts the conceptual understanding of shallow groundwater and river interactions at different locations, as well as any potential GDEs**.

[Section 3.1.8.1 Geologic Formations (p. 3-21 to 3-22)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The first aquitard is the extensive iron-silica hardpan layer of the Riverbank Formation, which is important in identifying where groundwater recharge can occur. The text states later in this section that the two clay layers, A and C clays are not present in the NKGSA area (p. 3-22). The E-clay, commonly known as the Corcoran Clay, is present in the western part of the NKGSA area and confined conditions exist below the Corcoran Clay. In the past, it was assumed that only one aquifer existed in the eastern part where the E-clay is absent. However, this assumption is being reevaluated. KDSA has described in Appendix 3A how locally extensive clay layers can function as an aquitard, forming a confined aquifer below. This evaluation will continue and NKGSA stated later in Section 5 that the confined aquifer may be monitored separately in the future. **Please discuss the importance of clearly defining which aquifer any given well is monitoring. Wells monitoring the unconfined aquifer measure the true water table and these elevations should be contoured separately. These groundwater elevations then help determine representative conditions within GDE units.**

[Section 3.1.8.2 Aquifer Characteristics and Properties (p. 3-26)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* In the NKGSA area, the base of the usable aquifer corresponds with the base of freshwater, generally defined as groundwater with total dissolved solids (TDS) of 2,000 milligrams per liter (mg/l) (KDSA, 2010), except one area to the east. In the far eastern part of the NKGSA area, the base of the aquifer is defined by the top of the basement complex. As noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** Properly defining the bottom of the basin will prevent the possibility of extractors with wells deeper than the basin boundary from claiming exemption from SGMA due to their well residing outside the vertical extent of the basin boundary.

[Section 3.1.12 Recharge and Discharge Areas (pp. 3-38 to 3-42)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* Wetlands were mapped along the Kings river, San Joaquin River, and several intermittent streams including Redbank Creek, Dog Creek, Pup Creek, and Big Dry Creek, as shown on Figure 3-22 (p. 3-43) as identified from US Forest Service's Wetland Inventory, according to the GSP. **In this section, please refer to the discussion of GDEs in Section 3.2.8 and mapped on Figure 3-40. Also, if the Wetland Inventory was in fact the US Fish and Wildlife Service (USFWS) National Wetlands Inventory (NWI), then correct the text and reevaluate the data. The NWI does not always include or segregate separate existing wetlands that are on the periphery of other features. Please describe the wetland types in more detail. If they are truly vernal pools confined by a clay layer then they are not GDEs, but they must meet the criteria of a vernal pool as described by the California Rapid Assessment Methodology or the United States Army Corps of Engineers to qualify.**

[Section 3.2.1 Groundwater Level Data (pp. 3-44 to 3-49)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The NKGSP notes that "The dramatic lowering of hydraulic heads in the confined parts of the aquifer has resulted in a large net downward movement of water through boreholes. This vertical flow occurs in both pumped and un-pumped wells during the growing season" (Faunt, CC ed. 2009) (p. 3-47). Vertical gradients have been measured recently indicating that there are head differences between wells screened above and below the Corcoran Clay in several locations. **Please refer to a map in this section to show the locations where the vertical gradients have been measured. Please expand this section to include a discussion of the impacts of vertical flow on ISWs and GDEs.**

<u>Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)</u>

[Section 3.2.7 Surface Water and Groundwater Interconnection (pp. 3-76 to 3-80)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* ISWs are best estimated by first determining which reaches are completely disconnected from groundwater. This approach would involve comparing groundwater elevations with a land surface Digital Elevation Model (DEM) that could identify which surface waters have groundwater consistently below surface water features, such that an unsaturated zone would separate surface water from groundwater. **Please provide or refer to depth to groundwater contour maps in this section. See Attachment D for best practices for completing this step. Specifically, ensure that the first step is contouring groundwater elevations, and the subtracting this layer from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape**. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found.

Contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make.

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". This GSP states that "the location specific data from the SJRRP indicate that there may be connection at some locations. Limited data is available from the DWR from shallow wells on ISW systems along the Kings River where it borders the NKGSA boundary" (p. 3-75). The locations along the San Joaquin River, where shallow wells are available (Figure 3-37, p. 3-77), are described, indicating that the river may be connected during times of high flows. No graphs were included to show the relationship between the depth to groundwater and the river bed. **Please provide cross-sections at these locations to show the relationship between the depth to groundwater and the bed of the river channel.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* Near the Kings River between Highway 180 and Sanger, shallow wells were installed at proposed gravel processing facilities and wastewater facilities by KDSA (KDSA 2017). The GSP states that the "KDSA further indicates that along the reach of the Kings River, upstream of the Reedley narrows, the groundwater is indicated to be in direct hydraulic communication with streamflow in the Kings River" (p. 3-79). The groundwater in this area is shallow based on DWR measurements. This finding needs to be illustrated using cross-sections with measured channel bed elevations and depths to groundwater. **Again, please provide a cross-section at this location to show the relationship between the depth to groundwater and the bed of the river channel.**

<u>Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)</u>

[Section 3.2.8 Groundwater Dependent Ecosystems (p. 3-81)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The NC dataset is a starting point for GSAs to identify GDEs in their basin/subbasin. The NC dataset has 1,959 acres of potential GDEs mapped within the NKGSA area, representing a significant amount of GDEs to be considered. Note that this is a starting point and not all potential GDEs are mapped and not all ecosystems mapped are GDEs. **Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled by the monitoring network**. Specifically, please note:
    - *[The GSA's response does not address our comment and no changes to GSP text made.]* Figure 3-23 provides groundwater depth contours for Spring of 2017. **Please provide more details on how this figure was developed by confirming**:

    - that wells monitoring the upper unconfined aquifer are being used to verify whether polygons in the NC dataset are supported by groundwater;
    - the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons reflect local conditions relevant to ecosystems;
    - the wells used for interpolating depth to groundwater are screened within the surficial unconfined aquifer and capable of measuring the true water table; and
    - depth to groundwater is contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a DEM to estimate depth to groundwater contours across the landscape. This will provide much more accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from measurements at wells assume that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate depth to groundwater using a DEM of the land surface to create the contour map.
- *[The GSA's response does not address our comment and no changes to GSP text made.]* It is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2017) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. **We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Ensure that groundwater condition data prior to the SGMA benchmark date of January 1, 2015 is included in the analysis. Please refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network**.
- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Please provide rationale for the 30-foot criteria cited in the text.** The text states (p. 3-81): "Recognizing that much of the Kings Subbasin has a depth to groundwater greater than the deepest vegetative GDE rooting depth of thirty feet, many of the GDEs identified in the NC Dataset Viewer were mischaracterized." In TNC's GDE Guidance, the depth criteria of 30 feet is presented as a criterion for *inclusion*, not a standalone criterion for *exclusion*. In other words, if groundwater is within 30 feet of the

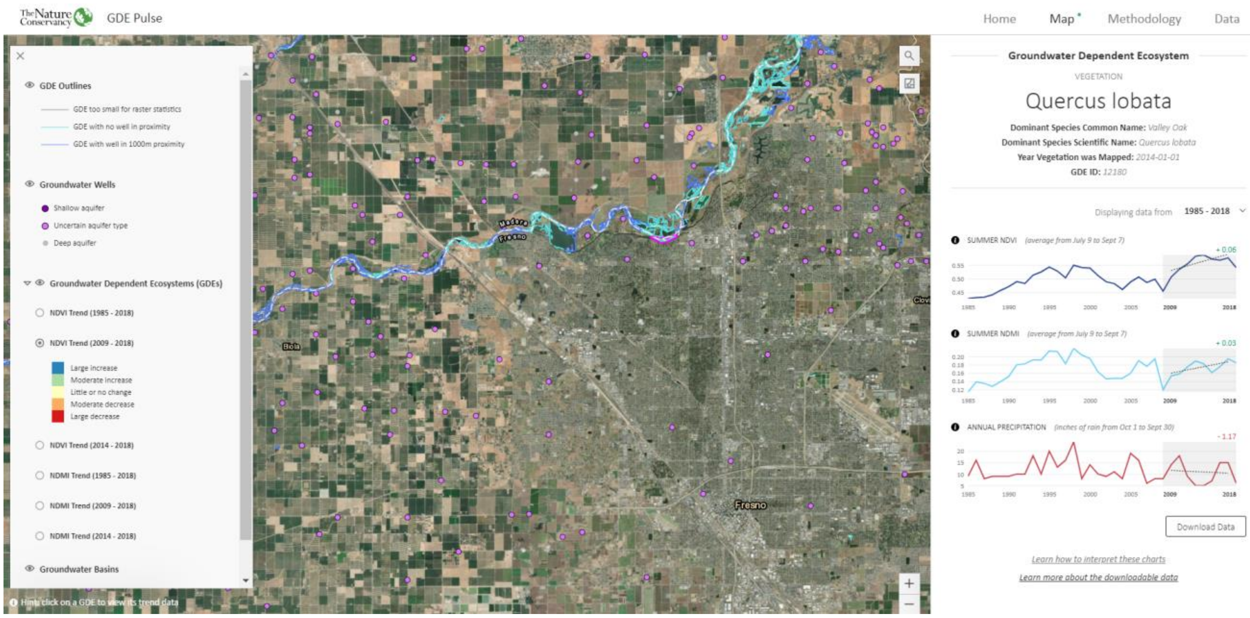
ground surface, then a GDE can be identified. If it is not, then further analysis must be conducted (see Appendix III of the GDE Guidance). **Please indicate what vegetation is present in all NC dataset polygons.** The actual rooting depth of vegetation growing in the area should be considered, and this will vary by species dominance and habitats present. For example, some phreatophytes can root to 120-feet deep in more arid and drought stressed environments. Furthermore, rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant. Maximum rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not like to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths.

  - *[One sentence added to GSP text: "This 100-ft buffer is based on a California Department of Transportation typical wetland setback (CDOT, 2019)." However, this addition to the text does not address our comment, nor does this buffer rule describe whether groundwater conditions in the basin are supporting GDEs.]* The text states: "The Kings Subbasin also categorized GDEs within 100 feet of the Kings River and the San Joaquin River as "Possible GDEs." **Please clarify how the 100-foot buffer was used to include or exclude GDEs in the NKGSA area, and how this is supported by groundwater level and plant physiological data. If there is a potential GDE near the river, we recommend that the entire GDE be included, rather than using an arbitrary 100-foot cutoff.**

<u>Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)</u>

[Section 3.2.8 Groundwater Dependent Ecosystems (p. 3-81)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present**. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment E of this letter for more details) or any other locally available data (e.g., leaf area index, evapotranspiration or other data) to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found within the NKGSA area:



- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Please provide an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes the vegetation types or habitat types and rank the GDEs as having a high, moderate or low value; and what characterizes the rank.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found or are expected to occur within any of the GDEs**. The list of freshwater species located in the Kings Subbasin can be found in Attachment C of this letter.
- *[The GSA's response does not address our comment and no changes to GSP text made.]* **For each identifiable GDE unit with supporting hydrological datasets please include the following:**
  - Plot and provide hydrological datasets for each GDE.
  - Define the baseline period in the hydrologic data.
  - Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater.
  - Explore cause-and-effect relationships between groundwater changes and GDEs.
- *[The GSA's response does not address our comment and no changes to GSP text made.]* **For each identifiable GDE unit without supporting hydrological datasets please describe data gaps and / or insufficiencies.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Compile and synthesize biological data for each GDE unit by including:**
  - Biological datasets for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.
  - Describe data gaps and insufficiencies.

- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Provide a description of the potential effects on GDEs, land uses, and property interests, including:**
    - Cause-and-effect relationships between GDE and groundwater conditions.
    - Potential impacts to GDEs that are considered to be "significant and unreasonable".
    - Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters, critical habitat constraints, etc.) for significant impacts to relevant species or ecological communities.
    - Land uses that and consider recreational uses (e.g., fishing/hunting, hiking, boating, etc.).
    - Property interests, such as privately and publicly protected conservation lands and opens spaces, wildlife refuges, parks, and natural preserves.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 3.3.6 Outflows from Groundwater System (p. 3-95)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* "Confined groundwater outflows were not calculated due to a lack of confined groundwater level information in NKGSA" (p. 3-99). This is a significant data gap. The confined outflow was estimated as 35,000 acre-feet per year (AF/year) based on data for other parts of the Kings Basin, compared to the total estimated outflow of 122,000 AF/year. **Please expand on how this data gap will be filled in the proposed monitoring program described in Section 5.**

[Section 3.3.8 Historical Water Budget (p. 3-101)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Please clarify whether a term is included for native or riparian vegetation evapotranspiration and for wetlands in the North Kings historical, current, and future water budgets.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* The groundwater outflow to McMullin GSA was estimated by comparing the flow before development in the 1920's to the present. The induced outflow was estimated to be 43,000 AF from the North Kings GSA to McMullin GSA (p. 3-102). This amount is stated as included in the historical water budget but not in future water budgets, since McMullin is expected to mitigate this imbalance from 2020 to 2040. However, the historical, current, and 2040 budgets had the same groundwater outflow of 122,000 AF/year. This seems inconsistent with the statement in the text. **Please revise or clarify the text as necessary.**

[Section 3.3.10 Projected Water Budget (p. 3-109)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The Friant Water Authority estimated climate change impacts on the San Joaquin River using the Water Storage Investment Program (WSIP) data sets. "In general, the data showed a slight reduction in future supplies" (p. 3-112). Given the uncertainty associated with the Kings River supplies in the future, the assumption was made that the historical water delivery from the Kings River would be maintained. **Please consider using the WSIP data to discuss potential impacts to groundwater conditions due to climate change on GDEs and aquatic ecosystems.**

Checklist Items 23 to 25 – Sustainability Goal (23 CCR §354.24)
[Section 4.1 Sustainability Goal (p. 4-2)] The Sustainability Goal does not consider GDEs or ISWs.

- *[Neither the GSA's response nor minor changes made to the GSP text adequately addresses our comment.]* **Since GDEs are likely present in the NKGSA area (see comments under Checklist Items 16-20) they should be recognized as beneficial users of groundwater and should be included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts should be included.**
- *[Neither the GSA's response nor minor changes made to the GSP text adequately addresses our comment.]* The Plan states that there are ISWs along the Kings River. In addition, there are multiple small creeks including Big Dry Creek, Pup Creek, Dog Creek, Redbank Creek, and Fancher Creek that may have ISWs. Further evidence that supports the presence of ISWs along these water courses include Figure 3-40 (p. 3-82) that identifies potential GDEs, and the depth to water measurements in wells for spring 1997 and 2012 presented in Appendix 3A (Technical Memorandum 4 Attachment 3). **Please identify and describe all ISWs for these areas and include them in the GSP.**
- *[Neither the GSA's response nor minor changes made to the GSP text adequately addresses our comment.]* GDEs are dependent, in part, on suitable water quality; however, the GSP only considers water quality for irrigation and domestic use. **TNC recommends including ISWs and their potential GDEs in the sustainability goal and criteria. Since GDEs may be affected by water quality, they should be included in the Sustainability Goal.**

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Sections 4.2.3 Measurable Objectives for Groundwater Levels (p. 4-18)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This Measurable Objective does not consider GDEs. GDEs are often adjacent to streams or associated with riparian corridors where ISWs exist, even if only seasonally or discontinuously along a longitudinal or lateral profile. **Please include GDEs (see comments under Checklist Items 8-10) in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.3 Measurable Objectives for Water Quality (p. 4-39)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This Measurable Objective does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.7.3 Measurable Objectives for Interconnected Surface Water and Groundwater (p. 4-72)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This Measurable Objective does not consider ISWs. **Please include ISWs (see comments under Checklist Items 16-20) in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

<u>Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28</u>)

[Sections 4.2.2 Minimum Thresholds for Groundwater Levels (p. 4-7)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This Minimum Threshold does not consider GDEs or ISWs. **Please include GDEs and ISWs in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.5.2 Minimum Thresholds for Groundwater Quality (p. 4-33)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This Minimum Threshold does not consider water quality needs of GDEs. **Please include a discussion about GDEs and water quality and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

[Sections 4.7.2 Minimum Thresholds for Interconnected Surface Water and Groundwater (p. 4-69)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This Minimum Threshold does not consider GDEs. GDEs are often adjacent to streams or associated with riparian corridors where ISWs exist, even if only seasonally or are discontinuous along a longitudinal profile. **Please include GDEs in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* The Plan states that there are time periods of ISWs along the San Joaquin River; however, they are dismissed because they are not continuously connected. ISWs that are not continuously connected spatially and/or temporally are still ISWs

and should not be excluded from this GSP. **Even when ISWs are not continuously connected they should be included in the Minimum Thresholds.**

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial uses and users of surface water that could be affected by groundwater withdrawals, including environmental users. The SJRRP identifies instream flow requirements for salmon in Reach 1a and potentially 2a which forms the northern border in the Plan area (http://www.restoresjr.net/about/overview-map/). **Please include instream flow requirements and critical habitat designations in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 4.2.1 Undesirable Results for Groundwater Levels (p. 4-3)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses and users that could be adversely affected by chronic groundwater level decline. **Please add "potential adverse impacts to GDEs and native freshwater species" to the list of potential undesirable results presented in Section 4.2.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* The GDE Pulse web application developed by TNC provides easy access to 35 years of remote sensing data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within and near the GSA. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture along the San Joaquin River and Kings River. An example screen shot from the GDE Pulse tool is presented under Checklist Items 11-15 above.

[Section 4.5.1 Description of Undesirable Results (for degraded water quality) (p. 4-29)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This section only describes undesirable results in terms of meeting drinking water standards. The following is a link to a paper by Smith, Knight and Fendorf (2018) titled "Overpumping leads to California groundwater arsenic threat": (https://www.nature.com/articles/s41467-018-04475-3). **The section should be modified to state that overpumping and dewatering of aquitards has been identified as a potential source of elevated arsenic concentrations above drinking water standards in San Joaquin Valley aquifers. In addition, any potential undesirable results from degradation of water quality that may impact GDEs and freshwater species in the area should be discussed in this section.**

[Section 4.7.1 Undesirable Results for Interconnected Surface Water and Groundwater (p. 4-57)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This section does not consider Undesirable Results for ISWs. The Plan states that there are time periods of ISWs along the San Joaquin River; however, they are dismissed because they are not continuously connected. **Even though the ISWs are not continuously connected they should be included in the Undesirable Results.** The analysis for potential depletion of ISWs in Section 4.7 should include all beneficial users of surface water that could be affected by groundwater withdrawals, including environmental. The SJRRP identifies instream flow needs for salmon in Reach 1a and potentially 2a which forms the northern border in the Plan area (http://www.restoresjr.net/about/overview-map/). **Please include instream flow requirements and critical habitat designations in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

Note some page numbers are cut off in Section 5. Page numbers refer to page of pdf document.

[Section 5.2 Groundwater Levels (pdf pp. 288 to 302)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* **Please address how the requirement to link and correlate groundwater level declines to biological responses, and significant and adverse impacts to GDEs and ISWs will be addressed by the monitoring network.**
- *[Our comment is adequately addressed through GSP text changes. Thank you for acknowledging that proper characterization of each individual aquifer zone is necessary for protection of beneficial users of groundwater.]* The proposed wells to be used for monitoring groundwater levels in the unconfined aquifer are shown in Figure 5-2 (p. 295). Many of the monitoring wells are missing well construction information. The missing well information is a known data gap and was acknowledged on p. 299. **To accurately characterize GDEs, please clarify how the unconfined aquifer will be monitored and how many wells will be used.**
- *[The GSA's response does not address our comment and no changes to GSP text made.]* The text states that the intent is to monitor the unconfined aquifer at present. "Groundwater level data from wells in the NKGSA will continue to be collected and evaluated to gain a better understanding of whether the confined groundwater conditions east of the Corcoran Clay are present" (p. 290). Wells that monitor the deeper confined or semi-confined aquifer will be added in the future. Monitoring of the confined aquifer may become a separate program in future years. **Please clarify how many of the wells on Figure 5-2 represent the unconfined aquifer.**

[Section 5.7 Depletion of Interconnected Surface Water (pdf pp. 325 to 331)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The NKGSA intends to use data from wells near the San Joaquin and Kings Rivers in the current monitoring network for depletion of ISWs monitoring. The data obtained by the SJRRP will be reviewed as it becomes available to supplement that well information. The long-term monitoring network shown on Figure 5-2 shows only a few wells that are near rivers and the well depths and screened intervals are not provided. **Please reconcile data gaps in monitoring for ISWs with specific recommendations (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features to improve ISW mapping and inform an adequate analysis.**

Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)
[Section 6.1 Introduction (p. 6-2) and 6.2 Projects (pp. 6-2 to 6-11)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* The NKGSA area includes many GDEs and ISWs (see our comments under checklist items 8-10 and 16-20 above) that are beneficial uses and users of groundwater, and may include potentially sensitive resources and protected lands. Environmental resource protection needs should be considered in establishing project priorities. In addition, and consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity as well as providing environmental benefits or benefits to disadvantaged communities. **Please include environmental benefits and multiple benefits as criteria for assessing project priorities.**

[Section 6.2 Projects (pp. 6-2 to 6-11)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This Section identifies many important projects; however, the descriptions for these projects only identify benefits to groundwater level and supply. Since maintenance or recovery of groundwater levels, or construction of recharge facilities, may have potential environmental benefits in many cases it would be advantageous to demonstrate multiple benefits from a funding and prioritization perspective.
    - **For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.**
    - If ISWs will not be adequately protected by those listed, **please include and describe additional management actions and projects targeted for protecting ISWs.**
    - Recharge ponds, reservoirs and facilities for managed stormwater recharge can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such multiple-benefit projects and facilities have been incorporated into local HCPs and NCCPs, more fully recognizing the value of the habitat that they provide and the species they support. For projects that

construct recharge ponds, **please consider identifying if there is habitat value incorporated into the design and how the recharge ponds will be managed to benefit environmental users.**
  - There are wetlands shown on Figure 3-19 (p. 3-37), which include recharge basins of the cities, irrigation districts, wastewater treatment facilities, and flood control district. **Please indicate whether the existing recharge basins are operated (or could be operated) as habitat suitable for migrating birds or other species and could be included in an HCP or NCCP.**
  - For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

[Section 6.3 Management Actions (p. 6-12)]

- *[The GSA's response does not address our comment and no changes to GSP text made.]* This section discusses the Management Actions for GSP implementation and SGMA compliance; however, these actions are focused on meeting groundwater level and supply measures and do not include support for GDEs or ISWs. **Please consider modifying the Management Actions to include education and outreach for protection of GDEs and ISWs, as well as specific management of these ecosystems and the species they provide for.**

Attachment C

Freshwater Species Located in the Kings Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Kings Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[4] as well as on The Nature Conservancy's science website[5].

Scientific Name	Common Name	Legally Protected Species		
		Federal	State	Other
Birds				
Actitis macularius	Spotted Sandpiper			
Aechmophorus clarkii	Clark's Grebe			
Aechmophorus occidentalis	Western Grebe			
Agelaius tricolor	Tricolored Blackbird	BCC	SCC	BSSC - First priority
Aix sponsa	Wood Duck			
Anas acuta	Northern Pintail			
Anas americana	American Wigeon			
Anas clypeata	Northern Shoveler			
Anas crecca	Green-winged Teal			
Anas cyanoptera	Cinnamon Teal			
Anas discors	Blue-winged Teal			
Anas platyrhynchos	Mallard			
Anas strepera	Gadwall			
Anser albifrons	Greater White-fronted Goose			
Ardea alba	Great Egret			
Ardea herodias	Great Blue Heron			
Aythya affinis	Lesser Scaup			
Aythya americana	Redhead		SCC	BSSC - Third priority
Aythya collaris	Ring-necked Duck			
Aythya marila	Greater Scaup

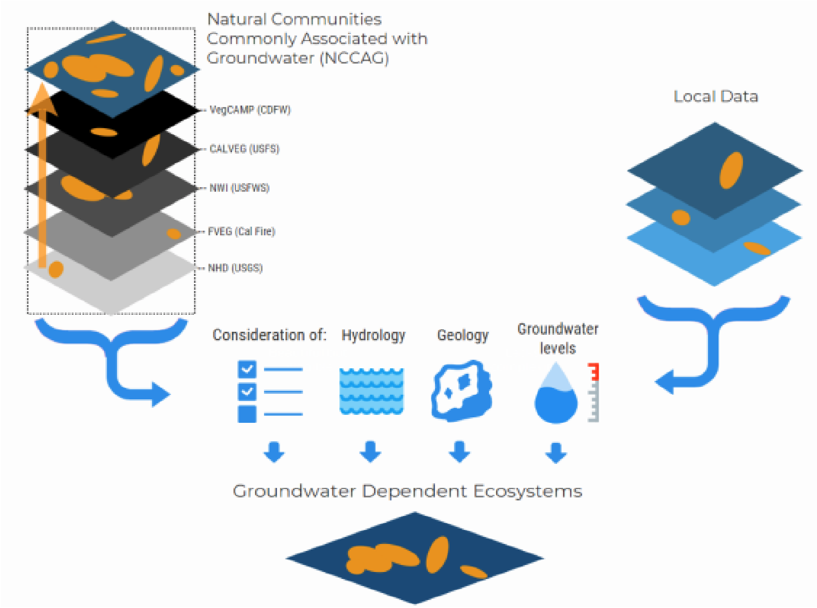
IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.



[6] *NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/*

[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

---

Mapping Indicators of Groundwater Dependent Ecosystems in California: Methods Report. San Francisco, California. Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/iGDE_data_paper_20180423.pdf

[9] "Groundwater Dependent Ecosystems under the Sustainable Groundwater Management Act: Guidance for Preparing Groundwater Sustainability Plans" is available at: https://groundwaterresourcehub.org/gde-tools/gsp-guidance-document/

[10] The Groundwater Resource Hub: www.GroundwaterResourceHub.org

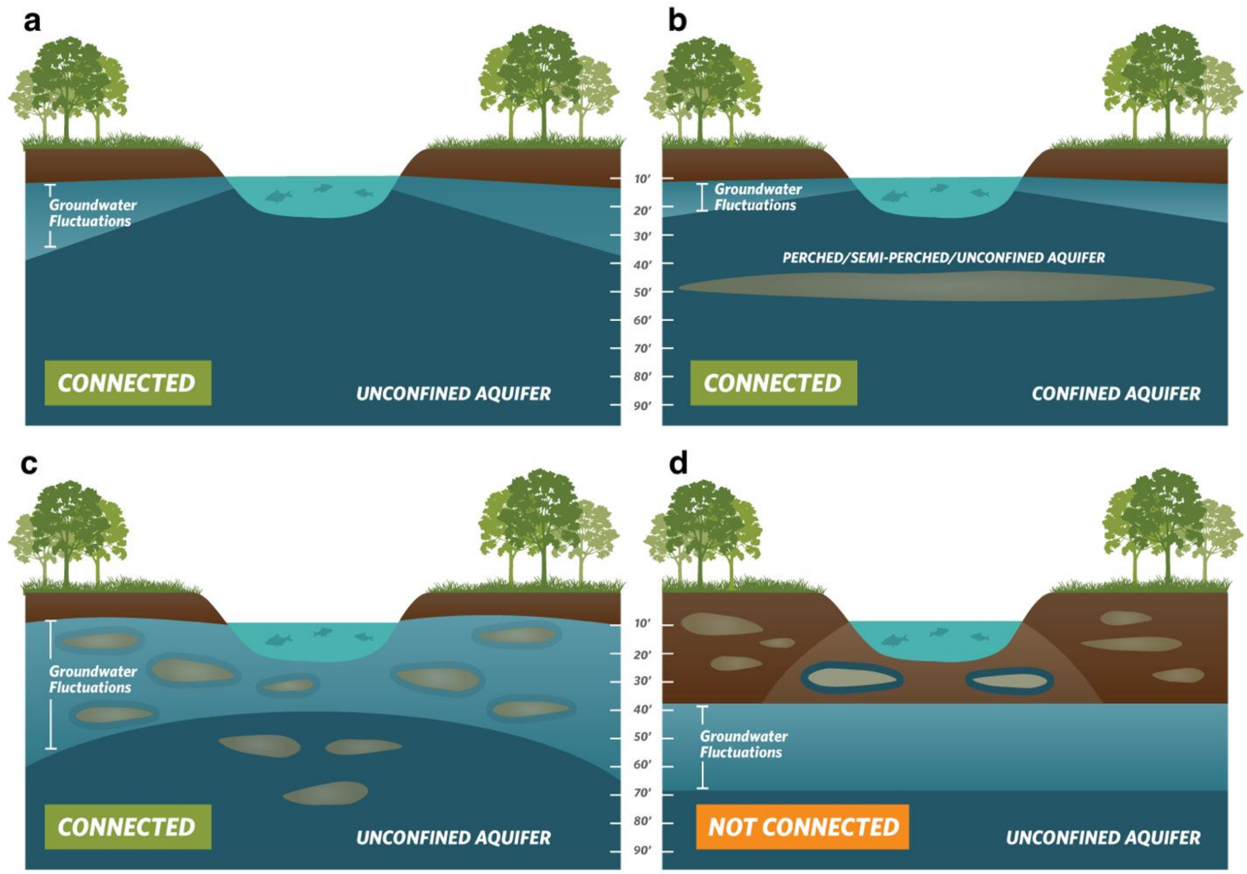


Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

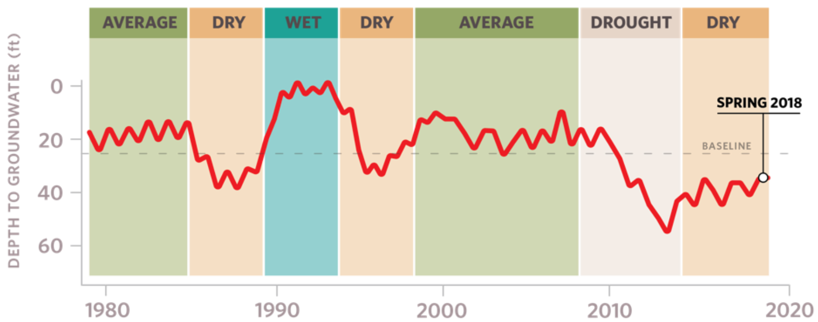

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[11] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

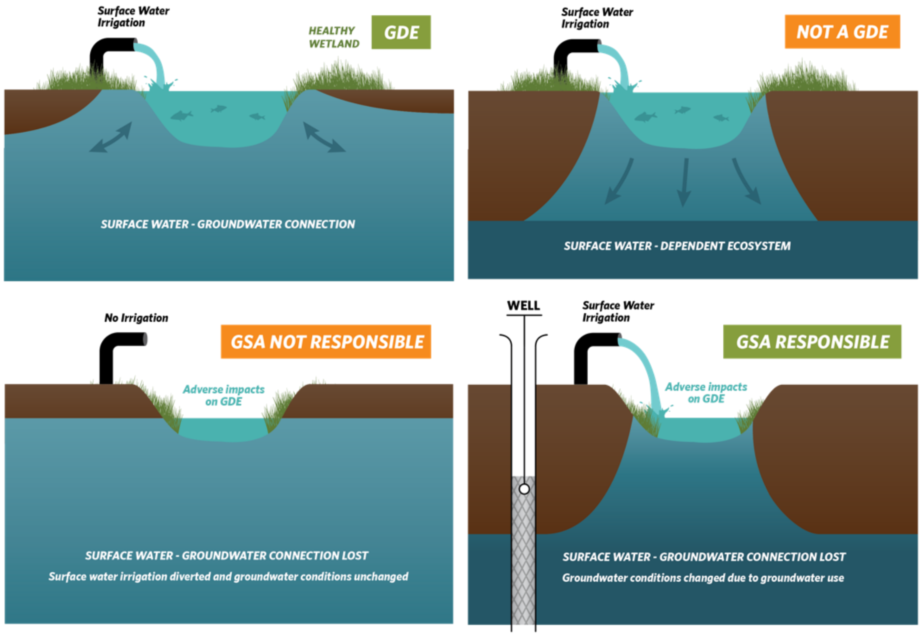

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

---

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

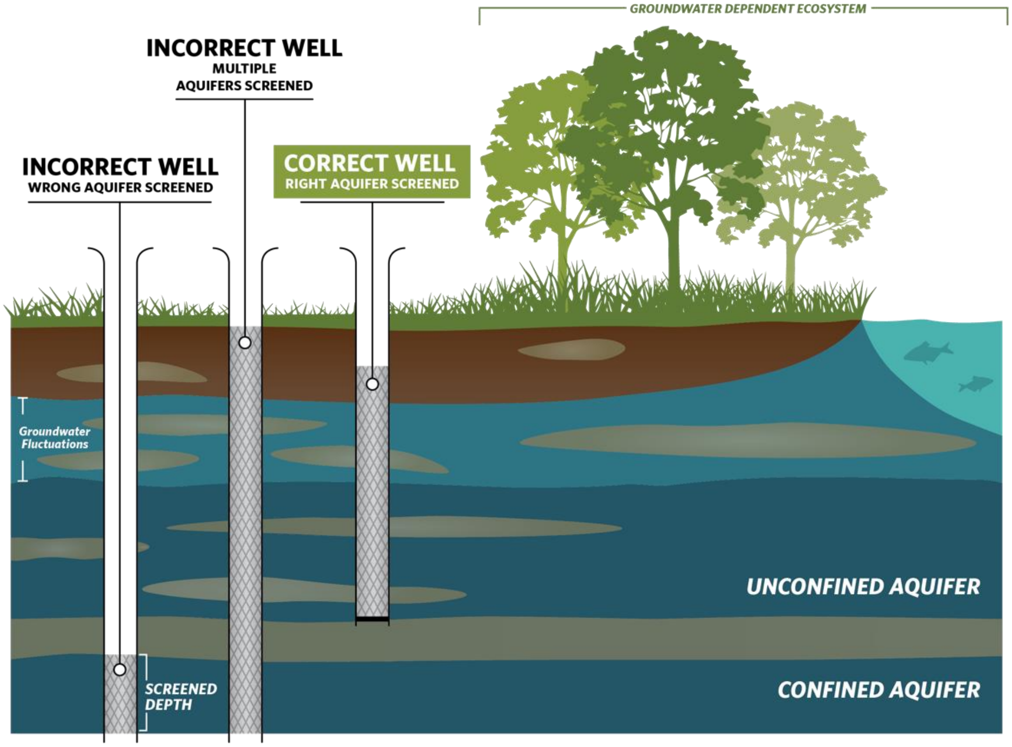

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

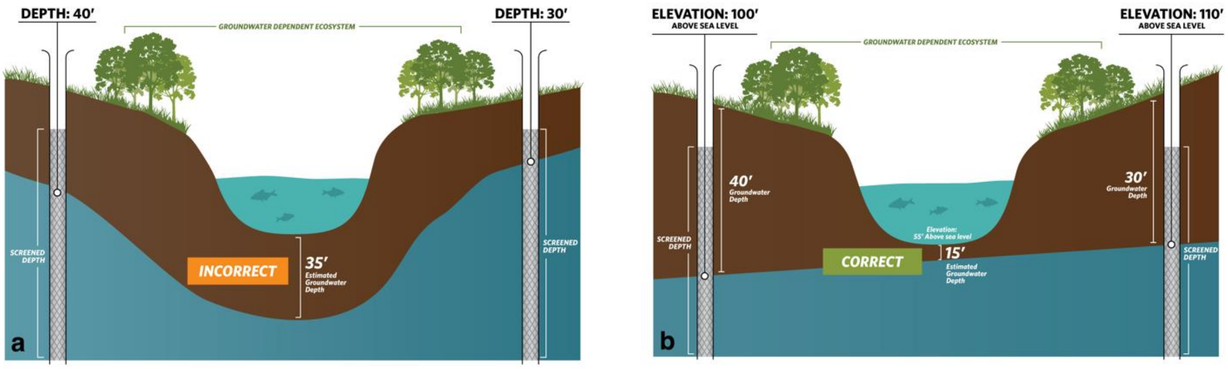

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

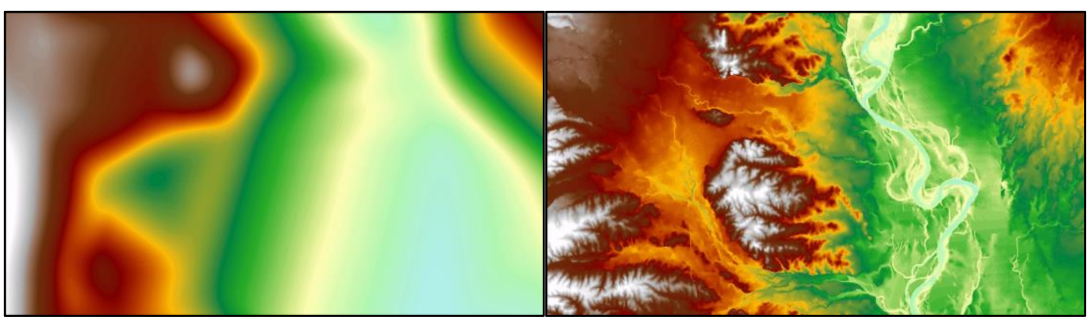

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[16] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

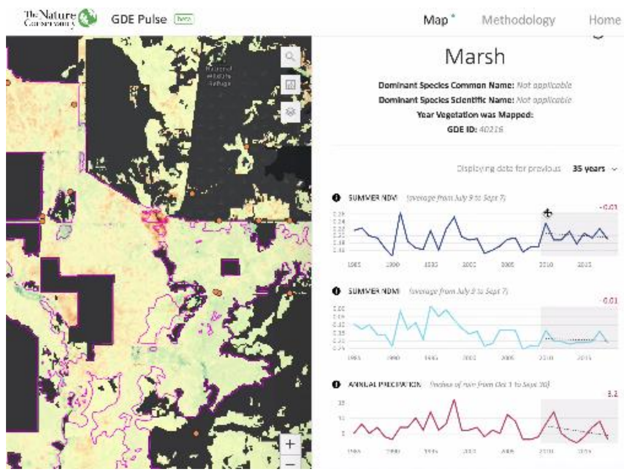
Attachment E

GDE Pulse

A new, free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data.

The Nature Conservancy
Protecting nature. Preserving life.

Visit https://gde.codefornature.org/



Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

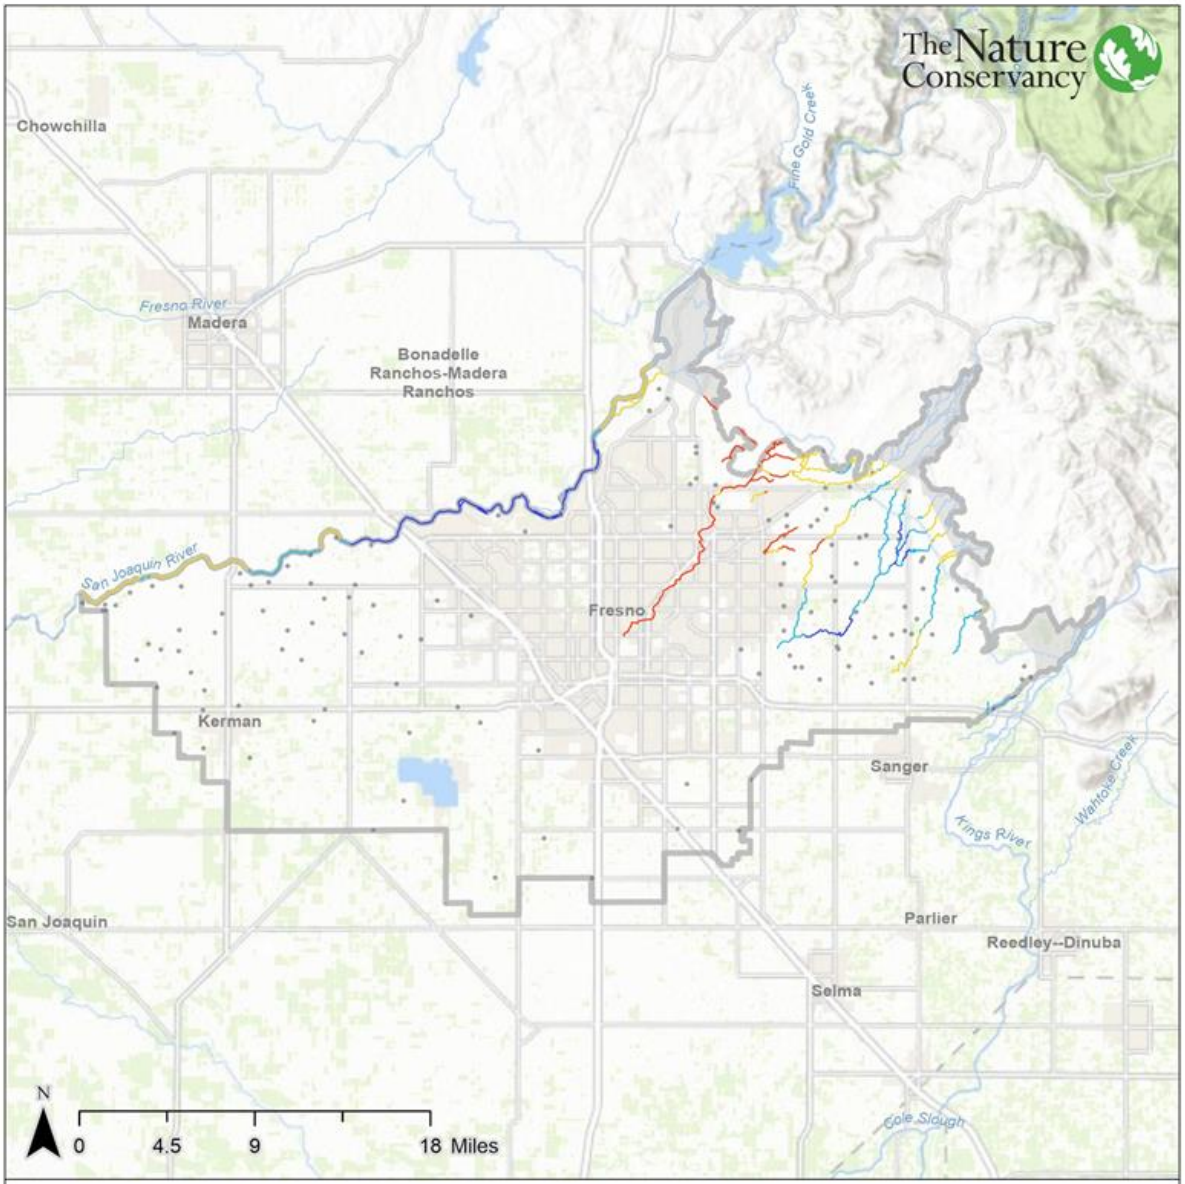
The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

Interconnected Surface Water: Minimum Groundwater Depth (2011-2018)

North Kings GSA GSP



Legend

- Groundwater Sustainability Agency (GSA)
- No groundwater depth data available
- Rivers and streams with no depth data (61.9 miles)
- Groundwater Elevation Monitoring Point

Minimum Groundwater Depth

- Connected - Gaining: Groundwater at or above stream surface (22.8 miles)
- Connected - Losing: Groundwater within 20 feet of stream surface (31.9 miles)
- Uncertain*: Groundwater within 20-50 feet of stream surface (44.5 miles)
- Likely Disconnected*: Groundwater greater than 50 feet below stream surface (23.7 miles)

**Streams could be connected to riparian or perched aquifers or shallow aquifers that are poorly characterized. More data are needed to confirm disconnected status.*

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Northern & Central Delta-Mendota Regions Groundwater Sustainability Plan (GSP), Delta Mendota Subbasin

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Northern and Central Delta-Mendota Regions Groundwater Sustainability Plan (GSP) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results, minimum thresholds and measurable objectives were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. SGMA's success is contingent upon avoiding undesirable results. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data. Attachment F provides a map and method summary of possible ISWs.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We appreciate that the GSP incorporated a portion of our feedback, however we disagree with the components where our feedback was ignored. This suggests a limited degree of engagement of environmental beneficial users and could result in a definition of sustainability that is biased towards a limited set of users in the basin. In our experience, the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (Emergency Regulations Section 355.4(b)(10).

TNC recommendation: We recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. In the spirit of continual improvement embedded in SGMA, we would like to offer the following input as areas for improvement in the next version of the GSP.

Interconnected Surface Waters (ISWs) – The GSP took steps towards identifying ISWs, however improvements should be made to identify gaining and losing reaches and/or to account for the spatial and temporal variations in stream depletions that are inherent with California's Mediterranean climate. These components are necessary to assess whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)).

The GSP analysis of ISW in their region (including a list of 10 sources used to identify the San Joaquin River as ISW) is largely consistent with our analysis of groundwater levels from 2011-2018 (see Attachment F). Our analysis also indicates that the streams stemming from the west side of the sub-basin are likely disconnected. However, these streams may be interconnected with riparian or perched aquifers, so additional monitoring should be required to confirm disconnection. Also, any area where a lack of shallow groundwater data makes the determination of ISWs uncertain should be identified as a data gap rather than being assumed to be disconnected. The regulations [23 CCR §351(o)] define ISWs as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted." "At any point" has both a spatial and temporal component. Even short durations of interconnection between groundwater and surface water can be crucial for surface water flow and support of GDEs.

Map and Assessment of potential ISWs:

By combining multiple years and seasons of groundwater depth data, The Nature Conservancy has determined that within the Northern and Central Delta-Mendota Region GSP, 58.9 river miles are gaining, 9.5 are losing, and the rest are uncertain or likely disconnected (based on streams with available groundwater depth data). Attachment F contains a one-page method summary and a GSP-specific map of ISWs. The interconnected surface water displayed on the map is based on the minimum groundwater depth estimated by the California Department of Water Resources between 2011 and 2018.

Note: In most cases, the groundwater depth data used to generate the ISW map does not include perched aquifers. As such, some streams marked as disconnected could in actuality, be connected.

<u>TNC recommendation:</u> TNC recommends obtaining additional shallow groundwater level data (and possibly installing additional shallow wells) and the installation of stream gages to obtain additional surface flow information to inform a thorough review of surface water-groundwater interconnectivity including estimation of the quantity and timing of streamflow depletions in the Subbasin. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 4,852 acres of potential GDEs occur in the GSA boundary. TNC developed the Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

TNC applauds the documentation of potential wetland and vegetative GDEs from TNC's and DWR's NC Dataset Viewer and the list of freshwater species for the Delta-Mendota Subbasin in the GSP. GDEs are plant and animal communities that require groundwater to meet some or all of their water needs. Establishing where GDEs exist on the landscape requires the use of spatial and temporal data including groundwater levels. The use of an arbitrary 100-foot boundary and reliance on the "professional judgement and local knowledge" to exclude potential GDEs is based on a generalized resource protection zone used by Caltrans to protect surface features and habitats from construction-related impacts, and is a common avoidance buffer related to permit requirements, Storm Water Pollution Prevention Plans (SWPPP), and/or CEQA/NEPA avoidance and minimization measures.

<u>TNC Recommendation</u>: TNC recommends that the GSA utilize groundwater level information to support the establishment of GDEs and elaborate on the correlation of groundwater level and plant physiological data to exclude potential GDEs. Although we appreciate the inclusion of this information; the information was not analyzed, elaborated on, no data gaps were identified, and no monitoring plan was put in place to specifically improve the understanding of GDEs.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and/or managed wetlands, as required under SGMA (Emergency Regulations Section 354.18(a) and (b)(3)). The GSP only focused on a subset of water use sectors, such as urban and agricultural users of groundwater. This is problematic because key environmental uses of groundwater are not being accounted for as

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

water supply decisions are made using this budget nor will they likely be considered in project and management actions.

TNC recommendation: As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). The GSP defined significant and undesirable results as a reduction in habitat productivity for the chronic lower of groundwater levels and reduction in groundwater storage SMCs. However, the minimum thresholds do not describe how a decline in groundwater level will affect GDEs and ISWs.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the GSP did not include a monitoring for that adequately characterizes the interaction of GDEs and other environmental beneficial users of surface water and groundwater, as required by 23 CCR §354.34. The GSP does not adequately characterize the interaction of GDEs and other environmental beneficial users of surface water and groundwater. GDEs are potentially located along surface water bodies where no shallow groundwater monitoring is proposed, leaving recognized data gaps unfilled. Therefore, GDEs and ISWs are not being specifically addressed by the monitoring network in the GSP.

TNC recommendation: The monitoring network should include: (1) additional monitoring to verify possible GDEs and reaches that include ISWs, (2) expanding the discussion of how monitoring data will be used to verify GDEs and ISWs, and (3) adding ecological monitoring to assess potential impacts to GDEs or ISWs.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers and balances the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto

Associate Director, California Water Program
The Nature Conservancy

Attachment A

Environmental User Checklist

The Nature Conservancy is neither dispensing legal advice nor warranting any outcome that could result from the use of this checklist. Following this checklist does not guarantee approval of a GSP or compliance with SGMA, both of which will be determined by DWR and the State Water Resources Control Board.

GSP Plan Element*		GDE Inclusion in GSPs: Identification and Consideration Elements	Check Box
Admin Info	**2.1.5 Notice & Communication** *23 CCR §354.10*	**Description of the types of environmental beneficial uses of groundwater that exist within GDEs and a description of how environmental stakeholders were engaged throughout the development of the GSP.**	1
Planning Framework	**2.1.2 to 2.1.4 Description of Plan Area** *23 CCR §354.8*	**Description of jurisdictional boundaries, existing land use designations, water use management and monitoring programs; general plans and other land use plans relevant to GDEs and their relationship to the GSP.**	2
		Description of instream flow requirements, threatened and endangered species habitat, critical habitat, and protected areas.	3
		Summary of process for permitting new or replacement wells for the basin, and how the process incorporates any protection of GDEs	4
Basin Setting	**2.2.1 Hydrogeologic Conceptual Model** *23 CCR §354.14*	**Basin Bottom Boundary:** Is the bottom of the basin defined as at least as deep as the deepest groundwater extractions?	5
		Principal aquifers and aquitards: Are shallow aquifers adequately described, so that interconnections with surface water and vertical groundwater gradients with other aquifers can be characterized?	6
		Basin cross sections: Do cross-sections illustrate the relationships between GDEs, surface waters and principal aquifers?	7
	2.2.2 Current & Historical Groundwater Conditions *23 CCR §354.16*	**Interconnected surface waters:**	8
		Interconnected surface water maps for the basin with gaining and losing reaches defined (included as a figure in GSP & submitted as a shapefile on SGMA portal).	9
		Estimates of current and historical surface water depletions for interconnected surface waters quantified and described by reach, season, and water year type.	10
		Basin GDE map included (as figure in text & submitted as a shapefile on SGMA Portal).	11

		If NC Dataset *was* used:	Basin GDE map denotes which polygons were kept, removed, and added from NC Dataset (Worksheet 1, can be attached in GSP section 6.0).	12
			The basin's GDE shapefile, which is submitted via the SGMA Portal, includes two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).	13
			GDEs polygons are consolidated into larger units and named for easier identification throughout GSP.	14
		If NC Dataset *was not* used:	Description of why NC dataset was not used, and how an alternative dataset and/or mapping approach used is best available information.	15
		Description of GDEs included:		16
		Historical and current groundwater conditions and variability are described in each GDE unit.		17
		Historical and current ecological conditions and variability are described in each GDE unit.		18
		Each GDE unit has been characterized as having high, moderate, or low ecological value.		19
		Inventory of species, habitats, and protected lands for each GDE unit with ecological importance (Worksheet 2, can be attached in GSP section 6.0).		20
	2.2.3 Water Budget *23 CCR §354.18*	Groundwater inputs and outputs (e.g., evapotranspiration) of native vegetation and managed wetlands are included in the basin's historical and current water budget.		21
		Potential impacts to groundwater conditions due to land use changes, climate change, and population growth to GDEs and aquatic ecosystems are considered in the projected water budget.		22
Sustainable Management Criteria	**3.1 Sustainability Goal** *23 CCR §354.24*	**Environmental stakeholders/representatives were consulted.**		23
		Sustainability goal mentions GDEs or species and habitats that are of particular concern or interest.		24
		Sustainability goal mentions whether the intention is to address pre-SGMA impacts, maintain or improve conditions within GDEs or species and habitats that are of particular concern or interest.		25
	3.2 Measurable Objectives *23 CCR §354.30*	**Description of how GDEs were considered and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.**		26
	3.3 Minimum Thresholds *23 CCR §354.28*	**Description of how GDEs and environmental uses of surface water were considered when setting minimum thresholds for relevant sustainability indicators:**		27
		Will adverse impacts to GDEs and/or aquatic ecosystems dependent on interconnected surface waters (beneficial user of surface water) be avoided with the selected minimum thresholds?		28
		Are there any differences between the selected minimum threshold and state, federal, or local standards relevant to the species or habitats residing in GDEs or aquatic ecosystems dependent on interconnected surface waters?		29
	3.4 Undesirable Results *23 CCR §354.26*	**For GDEs, hydrological data are compiled and synthesized for each GDE unit:**		30
		If hydrological data *are available* within/nearby the GDE	Hydrological datasets are plotted and provided for each GDE unit (Worksheet 3, can be attached in GSP Section 6.0).	31
			Baseline period in the hydrologic data is defined.	32

			GDE unit is classified as having high, moderate, or low susceptibility to changes in groundwater.	33
			Cause-and-effect relationships between groundwater changes and GDEs are explored.	34
		If hydrological data *are not available* within/nearby the GDE	Data gaps/insufficiencies are described.	35
			Plans to reconcile data gaps in the monitoring network are stated.	36
		For GDEs, biological data are compiled and synthesized for each GDE unit:		37
		Biological datasets are plotted and provided for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.		38
		Data gaps/insufficiencies are described.		39
		Plans to reconcile data gaps in the monitoring network are stated.		40
		Description of potential effects on GDEs, land uses and property interests:		41
		Cause-and-effect relationships between GDE and groundwater conditions are described.		42
		Impacts to GDEs that are considered to be "significant and unreasonable" are described.		43
		Known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities are reported.		44
		Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).		45
		Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.		46
Sustainable Management Criteria	**3.5 Monitoring Network** *23 CCR §354.34*	Description of whether hydrological data are spatially and temporally sufficient to monitor groundwater conditions for each GDE unit.		47
		Description of how hydrological data gaps and insufficiencies will be reconciled in the monitoring network.		48
		Description of how impacts to GDEs and environmental surface water users, as detected by biological responses, will be monitored and which GDE monitoring methods will be used in conjunction with hydrologic data to evaluate cause-and-effect relationships with groundwater conditions.		49
Projects & Mgmt Actions	**4.0. Projects & Mgmt Actions to Achieve Sustainability Goal** *23 CCR §354.44*	Description of how GDEs will benefit from relevant project or management actions.		50
		Description of how projects and management actions will be evaluated to assess whether adverse impacts to the GDE will be mitigated or prevented.		51

Attachment B

TNC Evaluation of the
Northern & Central Delta-Mendota Regions Groundwater Sustainability Plan

The Northern and Central Delta-Mendota Regions Groundwater Sustainability Plan (GSP), adopted November 2019 as Resolution 2019-0733, was reviewed by TNC. TNC submitted comments on the Public Draft GSP on October 10, 2019. However, responses to comments on the public draft were not publicly available so we compared the Public Draft GSP to the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the GSA during the public comment period, and states whether or not they were addressed in the Final GSP *[as green text in brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

Checklist Item 1 - Notice & Communication (23 CCR §354.10)

[Section 4.1 Description of Beneficial Uses and Users in Plan Area (pp. 4-1 to 4-3)]

- *[Our comment was not addressed. No changes to GSP text made.]* The California Water Code §1305(f) defines that beneficial uses of waters of the State include "preservation and enhancement of fish, wildlife, and other aquatic resources and preserves" (p. 4-1). Table 4-1 lists beneficial uses and user stakeholder groups (pp. 4-2 to 4-3) and includes federal and state lands and facilities; environmental agencies and groups; rivers, creeks, and recreational and wildlife refuges; and recreational areas in addition to the direct users of groundwater and surface water. The GSP noted further refinement of the Table 4-1 list will be made by 2025. Please describe whether other beneficial uses and users of groundwater in the Subbasin are present: Protected Lands, including conservation areas and other protected lands; and Public Trust Uses including wildlife, aquatic habitat, fisheries, and recreation.
- *[Our comment was not addressed. No changes to GSP text made.]* The types and locations of environmental uses, species and habitats supported, and the designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the Subbasin should be specified. Please identify environmental users, and refer to the following:
    - Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/
    - The list of freshwater species located in the Delta-Mendota Subbasin in Attachment C of this letter. Please take particular note of the species with protected status.

Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8)

[Section 2.2.1 General Plans in Plan Area (p. 2-42 to 2-66)]

- *[Our comment was not addressed. No changes to GSP text made.]* Figure 2-26 (p. 2-43) shows the area covered by city, community, and county general plans. There are five county plans, one city plan, and three community plans that cover a portion of the Northern and Central Delta-Mendota Regions. The plans should be modified to include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, aquatic resources and other GDEs and ISWs.
- *[Our comment was not addressed. No changes to GSP text made.]* In general, the plans seek to protect riparian habitat. This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. Please identify all relevant HCPs and NCCPs within the Subbasin and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.
- *[Our comment was not addressed. No changes to GSP text made.]* Please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.

[Section 2.1.2.2 Major Water-Related Infrastructure (p. 2-10 to 2-12)]

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP provides a description of the major water infrastructure projects including the Central Valley Project, the State Water Project, and the Tracy Fish Collection Project, however there is no discussion of any in-stream flow requirements. Please describe any current or planned in-stream flow requirements of the San Joaquin and Merced Rivers or any of the westside creeks.

[Section 2.3.2 County Well Construction/Destruction Standards and Permitting (p. 2-77)]

- *[Our comment was not addressed. No changes to GSP text made.]* Table 2-7 (p. 2-78) summarizes well permitting requirements and county ordinances for the counties of Fresno, San Benito, Merced, Stanislaus, and San Joaquin. The counties have ordinances that limit groundwater export and several counties have ordinances that minimize unsustainable groundwater extraction. Please include a discussion of the following in this section:
  - Future well permitting must be coordinated with the GSP to assure achievement of the Plan's sustainability goals.

[2] Available online at: https://groundwaterresourcehub.org/sgma-tools/the-critical-species-lookbook/

- The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). The need for well permitting programs to comply with this requirement should be stated in the text.

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 5.2.5.2 Definable Bottom of Basin (p. 5-12)]

- *[Our comment was not addressed. No changes to GSP text made.]* Defining the bottom of Subbasin based on geochemical properties is a suitable approach for defining the base of freshwater, however, as noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom. This will prevent the possibility of extractors with wells deeper than the basin boundary (defined by the base of freshwater) from claiming exemption of SGMA due to their well residing outside the vertical extent of the basin boundary.

[Section 5.2.6.1 Principal Aquifers (p. 5-12 to 5-14)]

- *[Our comment was not addressed. No changes to GSP text made.]* The very shallow unconfined groundwater falls under DWR's definition of a principal aquifer, which is defined as "aquifer or aquifer system that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems" [*23 CCR §351(aa)*]. Thus, disregarding this shallow groundwater as a principal aquifer due to its "shallow nature and high salinity" is inadequate. This is especially true in the places where projects to develop the shallow groundwater may be considered for use on more salt-tolerant crops. SGMA requires GSAs to sustainably manage groundwater resources in all aquifers, especially if groundwater use and management can result to impacts on beneficial uses and users. Please refer to Best Practice #1 in Attachment C for further explanation and accompanying graphics.

[Section 5.2.6.2 Aquifer Properties p. 5-14 to 5-31]

- *[Our comment was not addressed. No changes to GSP text made.]* Regional basin-wide geologic cross sections are provided in Figures 5-7 through 5-16 (p. 5-15 to 5-27). These cross-sections do not include a graphical representation of the manner in which the very shallow groundwater or perched water may interact with ISWs or GDEs that would allow the reader to understand this topic. Please include example near-surface cross section details that depict the conceptual understanding of shallow groundwater and stream interactions at different locations, including the perched aquifer and the Upper Aquifer.

- *[Our comment was not addressed. No changes to GSP text made.]* The two-aquifer system is separated primarily by the Corcoran Clay, which has a variable depth as shown on Figure 5-17 (p. 5-28). The Corcoran Clay is absent in the far western parts of the Subbasin. There is also a Very Shallow unconfined groundwater zone, and perched water is sometimes present due to fine-grained clay layers. Please provide a map showing where the Very Shallow groundwater zone and the perched aquifers are located.

[Section 5.3.2.4 Groundwater Trends (p. 5-92 to 5-118)]

- *[Our comment was not addressed. No changes to GSP text made.]* Data gap areas for the Upper Aquifer, Lower Aquifer, or both are shown in Figure 5-64 (p. 5-96). Much of the data gaps area is located within the Northern and Central Delta-Mendota Regions. There are very few wells screened in the Upper Aquifer shown in the groundwater contour map in Spring 2013 and Fall 2013, as shown on Figures 5-80 and 5-81, within the Northern and Central Delta-Mendota Regions. Please explain how these data gaps will be filled or refer to a section later in the GSP.
- *[Our comment was not addressed. No changes to GSP text made.]* Well hydrographs are shown for wells screened in the Very Shallow Groundwater in Figure 5-67 (p. 5-99). Please indicate which of these wells are located within the Northern and Central Delta-Mendota Regions.
- *[Our comment was not addressed. No changes to GSP text made.]* The GSP states (p. 5-94) that vertical gradients are restricted by the Corcoran Clay. In the western part of the Subbasin, interfingering clay layers minimize downward gradients, except where the clay has been compromised by the construction of composite wells. Please provide data or analysis to explain and substantiate the vertical gradients noted in the text.

<u>Checklist Items 8, 9, and 10 – Interconnected Surface Waters (ISW) (23 CCR §354.16)</u>

[Section 5.3.7 Interconnected Surface Water Systems (p. 5-170 to 5-172)]

- *[Our comment was not addressed. No changes to GSP text made.]* The regulations [23 CCR §351(o)] define ISW as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. ISWs can be either gaining or losing. The text states (p. 5-170) "Streams stemming from the west side of the Delta-Mendota Subbasin are ephemeral in nature, and only two of these creeks reach the San Joaquin River (Del Puerto Creek and Orestimba Creek). These creeks lose their flows to the underlying vadose zone (net-losing streams) and therefore do not represent areas of potential GDEs." No evidence is provided in the Plan that states that these streams are not connected to the upper-most aquifer along some portion of the drainage for some time period. TNC disagrees with the statement that these westside ephemeral streams do not represent areas of potential GDEs, without data or analysis provided. Please reconcile data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features in the Monitoring Network section of the GSP to improve ISW mapping in future GSPs.

- *[Our comment was not addressed. No changes to GSP text made.]* Please provide more detail on how the quantity of gains and/or depletions from the groundwater at each reach of the San Joaquin River was determined. For example, were the values taken from the cited literature sources or determined from further analysis or modeling? Please provide or refer to a map that shows the designated reaches listed in Table 5-9.

Checklist Items 11 to 15, Identifying and Mapping GDEs (23 CCR §354.16)

[Section 5.3.7.6 Groundwater Dependent Ecosystems (p. 5-172)]

- *[Our comment was not addressed. No changes to GSP text made.]* The text states (p. 5-172): "To further screen available information regarding GDEs, the following standards were set for identifying GDEs in the Northern and Central Delta-Mendota Regions: (1) areas with depths to groundwater levels greater than 30 feet were eliminated unless the vegetation identified in those areas were consistent with species with deep root systems (e.g. live oaks); (2) seasonally-managed areas and wetlands were eliminated due to their dependence on applied surface water; and (3) a 100-foot buffer was applied around the San Joaquin River within the Northern Delta-Mendota Region to include all communities in the NCCAG dataset as potential GDEs, except where professional judgement and local knowledge determined GDEs were not present." The three standards are discussed in turn below.
- *[Our comment was not addressed. No changes to GSP text made.]* The following comments apply to *Standard (1): Areas with depth to groundwater greater than 30 feet in Spring 2015, unless the vegetation identified in those areas were consistent with species with deep root systems (e.g. live oaks).*
    - *[Our comment was not addressed. No changes to GSP text made.]* While depth to groundwater levels within 30 feet are generally accepted as being a proxy for confirming that polygons in the NC dataset are connected to groundwater, it is highly advised that seasonal and interannual groundwater fluctuations in the groundwater regime are taken into consideration. Utilizing groundwater data from one point in time (e.g., Spring 2015) can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Based on a study we recently submitted to Frontiers in Environmental Science Journal, we've observed riparian forests along the Cosumnes River to experience a range in groundwater levels between 1.5 and 75 feet over seasonal and interannual timescales. Seasonal fluctuations in the regional water table can support perched groundwater near an intermittent river that seasonally runs dry due to large seasonal fluctuations in the regional water table. While perched groundwater itself cannot directly be managed due to its position in the vadose zone, the water table position within the regional aquifer (via pumping rate restrictions,

restricted pumping at certain depths, restricted pumping around GDEs, well density rules) and its interactions with surface water (e.g., timing and duration) can be managed to prevent adverse impacts to ecosystems due to changes in groundwater quality and quantity under SGMA. We highly recommend using depth to groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. Please refer to Attachment C of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network. Additionally, Spring 2015 is after the SGMA benchmark date of January 1, 2015. Please include groundwater condition data prior to the SGMA benchmark date in the analysis.

- *[Our comment was not addressed. No changes to GSP text made.]* Please confirm that wells screened in the Upper Aquifer are being used to verify whether NCCAGs are actual GDEs, given the significant data gap areas noted on Figure 5-64 (page 5-96). Using "depth to groundwater" measurements from confined aquifers is mapping piezometric head of the confined aquifer and not detecting groundwater conditions in the principal aquifers of the unconfined aquifer that are supporting the ecosystem. If there is insufficient groundwater level data in the Upper Aquifer, then the NCCAGs in these areas should be included as GDEs in the GSP until data gaps are reconciled in the monitoring network.
- *[Our comment was not addressed. No changes to GSP text made.]* Please provide depth to groundwater contour maps and note the following best practices for doing so.
  - i) Are the wells used for interpolating depth to groundwater sufficiently close (<5km) to NC Dataset polygons to reflect local conditions relevant to ecosystems?
  - ii) Are the wells used for interpolating depth to groundwater screened within the surficial unconfined aquifer and capable of measuring the true water table (see comment b above)?
  - iii) Is depth to groundwater contoured using groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape? This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found. Depth to groundwater contours developed from depth to groundwater measurements at wells assumes that the land surface is constant, which is a poor assumption to make. It is better to assume that water surface elevations are constant in between wells, and then calculate

depth to groundwater using a DEM of the land surface to contour depth to groundwater.

  - *[Our comment was not addressed. No changes to GSP text made.]* Please use care when considering rooting depths of vegetation. Please list the species in each GDE, and whether the GDE was eliminated or retained based on the 30-foot standard and provide evidence for the decision. While Valley Oak (*Quercus lobata*) have been observed to have a max rooting depth of ~24 feet (https://groundwaterresourcehub.org/gde-tools/gde-rooting-depths-database-for-gdes/), rooting depths are likely to spatially vary based on the local hydrologic conditions available to the plant. Also, max rooting depths do not take capillary action into consideration, which will vary with soil type and is an important consideration since woody phreatophytes generally do not prefer to have their roots submerged in groundwater for extended periods of time, and hence can access groundwater at deeper depths.

- *[Our comment was not addressed. No changes to GSP text made.]* The following comment applies to *Standard (2): Habitat areas with supplemental water*. The application of supplemental water to managed wetlands <u>does not preclude</u> the possibility that NC polygons could be accessing groundwater in addition to the supplied water. In the scientific literature, it is generally acknowledged that GDEs can rely on groundwater for <u>some or all</u> of their requirements. GDEs can rely on multiple water sources simultaneously and at different temporal/spatial scales (e.g., precipitation, river water, reservoir water, soil moisture in the vadose zone, groundwater, applied water, treated wastewater effluent, urban stormwater, irrigated return flow). SGMA defines GDEs as "ecological communities and species that depend on groundwater <u>emerging from aquifers</u> or on groundwater <u>occurring near</u> the ground surface". Hence, we recommend that depth to groundwater contour maps are used to identify whether a connection to groundwater exists for the managed wetlands in the Northern and Central Delta-Mendota Regions. Please refer to Attachment C of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.
- *[Our comment was not addressed. No changes to GSP text made*. Caltrans standards under the Coastal Act were cited to support Standard (3), but these standards apply to a generalized resource protection zone related to construction activities and avoidance of construction impacts to surface features and habitat, not groundwater dependent ecosystems.] The following comment applies to *Standard (3): 100-foot buffer area applied around the San Joaquin River.* We disagree with the use of an arbitrary 100-foot cutoff and reliance on the "professional judgement and local knowledge". Instead, please explain how this criterion is supported by groundwater level and plant physiological data to exclude potential GDEs near the river.
- *[Our comment was not addressed. No changes to GSP text made.]* On p. 5-176 the GSP states, "Possible GDEs have also been identified along streams originating from the Coast Range; however, these areas are topographically disconnected from the Subbasin's principal aquifers and are located in areas of de minimus or zero groundwater use and are therefore are unmanageable through the Sustainable Groundwater Management Act (SGMA)." Please provide further information on the

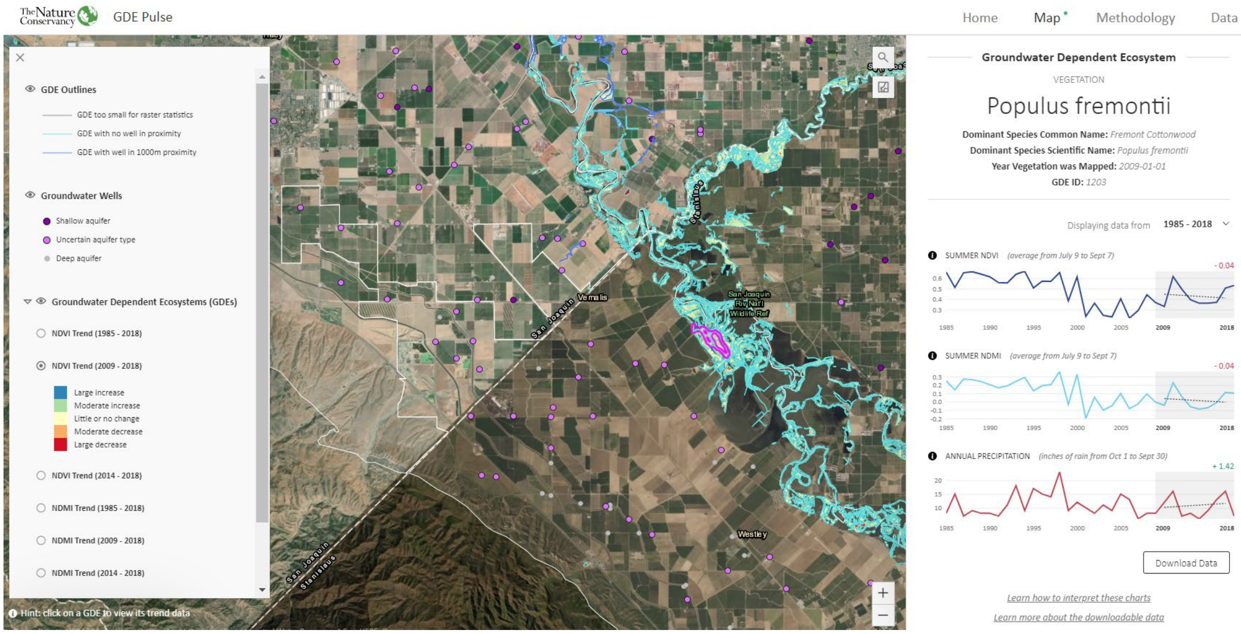
analysis of GDEs on westside streams, including citing field studies or modeling studies that show the disconnected nature of these streams. Indicate on which streams GDE polygons were excluded and on which streams GDE polygons were retained. Identify any data gaps and ensure that GDE polygons are retained until data gaps are reconciled.

- [Our comment has been adequately addressed through GSP text changes. Figures 5-118 and 5-119 were modified to enhance visualization of categories by modifying the map symbology to clearly demarcate the GSP region and potential GDEs.] On Figures 5-118 and 5-119, it's difficult to distinguish the colors underneath the hatching, and thus see which categories apply to the Northern and Central Delta-Mendota Regions. Consider changing the hatching pattern or supplying a map for just the Northern and Central Delta-Mendota Regions. Please be more specific when denoting "mapping error" (p. 5-176). The basin's GDE shapefile, which is submitted via the SGMA Portal, should also include two new fields in its attribute table denoting: 1) which polygons were kept/removed/added, and 2) the change reason (e.g., why polygons were removed).

Checklist Items 16 to 20, Describing GDEs (23 CCR §354.16)

[Section 5.3.7.6 Groundwater Dependent Ecosystems (p. 5-172)]

- *[Our comment was not addressed. No changes to GSP text made.]* Please provide information on the historical or current groundwater conditions in the GDEs or the ecological conditions present. Refer to GDE Pulse (https://gde.codefornature.org; See Attachment D of this letter for more details) or any other locally available data (e.g., leaf area index, evapotranspiration or other data) to describe depth to groundwater trends in and around GDE areas, as well as trends in plant growth (e.g., NDVI) and plant moisture (e.g., NDMI). Below is a screenshot example of data available in GDE Pulse for NC dataset polygons found in the Northern and Central Delta-Mendota Regions.



- *[Our comment was not addressed. No changes to GSP text made.]* Please provide an ecological inventory (see Appendix III, Worksheet 2 of the GDE Guidance) for all potential GDEs that includes the vegetation types or habitat types and rank the GDEs as having a high, moderate or low value; and what characterizes the rank.
- [Table 5-10 in the GSP includes the list of freshwater species located in the Delta-Mendota Subbasin that was included in Attachment C of TNC's December 10, 2019 comment letter to the draft GSP. We appreciate the inclusion of this information; however, the information was not analyzed, elaborated on, and no data gaps were identified.] Please identify whether any endangered or threatened freshwater species of animals and plants, or areas with critical habitat were found in or near any of the GDEs since some organisms rely on uplands and wetlands during different stages of their lifecycle. Resources for this include the list of freshwater that can be found in Table 5-10 of the GSP. Additional resources include the Critical Species Lookbook and CDFW's CNDDB database.

<u>Checklist Items 21 and 22 – Water Budget (23 CCR §354.18)</u>

[Section 5.4 Water Budgets (p. 5-181 to 5-235)]

- *[Our comment was not addressed. No changes to GSP text made.]* Evapotranspiration is included as an outflow category in the land surface budget; however, it is not split between type of evapotranspiration. Please separate this term by land-use type (for example, agricultural; municipal and domestic; and native and riparian).
- *[Our comment was not addressed. No changes to GSP text made.]* Groundwater outflow to ET does not appear to be identified as a groundwater budget component. Since GDEs (including wetlands, riparian vegetation, phreatophytes and other

communities) are recognized as beneficial users of groundwater in the Northern and Central Delta-Mendota Regions, it is appropriate to include them in these calculations.

Checklist Item 23-26 Sustainability Goal (23 CCR §354.24)

[Section 6.2 Sustainability Goal (p. 6-2)]

- *[Our comment was not addressed. No changes to GSP text made.]* Since GDEs are present within the Subbasin (please see comments under checklist items 16-20) they should be recognized as beneficial users of groundwater and should be included in the Sustainability Goal. In addition, a statement about any intention to address pre-SGMA impacts to GDEs and ISWs should be included here and within the interim milestones and measurable objectives. Request that the connectivity of GDEs and ISWs to each aquifer be made clear. If we are talking about connectivity to the very shallow surficial aquifer we also need to establish if its current and, or future management to determine if it is a principal aquifer and therefore should be included in the sustainability goal and sustainability criteria. If it isn't a principal aquifer, please add statements that the future protection of GDEs would be incorporated into the 5-yr update as future management plans are developed.
- *[Our comment was not addressed. No changes to GSP text made.].*] The GSP states that there are time periods of ISW connectivity along the San Joaquin River on the northern end of the basin. Please include protection of ISWs as a part of the Sustainability Goal.
- *[Our comment was not addressed. No changes to GSP text made.]* GDEs are dependent, in part, on suitable water quality; however, this GSP only considers water quality for irrigation and domestic use. Since GDEs may also be affected by water quality they should be included in the Sustainability Goal.

Checklist Item 26 – Measurable Objectives (23 CCR §354.30)

[Section 6.3.1.3 Measurable Objectives for Groundwater Levels (p. 6-10)]

- *[Our comment was not addressed. No changes to GSP text made.]* This Measurable Objective does not consider GDEs. Please include GDEs (see comments under Checklist Items 16-20) in this section and whether the measurable objectives and interim milestones will help achieve the sustainability goal as it pertains to the environment.

[Section 6.5.3 Measurable Objectives for Water Quality (p. 4-29)]

- *[Our comment was not addressed. No changes to GSP text made.]* This Measurable Objective does not consider water quality needs of GDEs. Please modify this section to specifically address degraded water quality from total dissolved solids (TDS), arsenic (As), boron (B), and other potential constituents of concern to wildlife and vegetation communities of GDEs.

[Section 6.3.6.3 Measurable Objectives and Interim Milestones (for Interconnected Groundwater Surface Water Systems) (p. 6-35)]

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP states that depletions will be considered from monitoring data collected in 2020 to 2025 and proposes a qualitative statement of no increased depletions. Based on statements made in Chapter 5, Sections 5.3.7 (pp. 5-170 to 5-173), this GSP only considers gaining and losing reaches of the San Joaquin River as being potentially interconnected (See Table 5-9 on p. 5-172). There are several ephemeral streams that may reach the San Joaquin in a given year that are dismissed because they are not regularly connected and, or flow is ephemeral. Streams that are not continuously connected spatially and, or temporally, or are ephemeral in nature, are still potential ISWs and should not be excluded from this GSP. Ephemeral water courses in the basin include Orestimba Creek, Del Puerto Creek, Mercy Creek, Hospital Creek, Inghram Creek Salado Creek, and Cow Creek. For example, on page 4-7 in the *Stanislaus County Hydrologic Model: Development and Forecast Modeling* (Stanislaus County, California) it states "data from nearby calibration wells suggests that in fact Orestimba Creek is groundwater connected and gaining in its middle and lower reaches". Because the question of ISWs is a data gap, it needs to be acknowledged and a plan to reconcile the data gap specified. Even though the streams may not be continuously connected, they may still be ISWs, and should be included in the Measurable Objectives.

<u>Checklist Item 27-29 – Minimum Thresholds (23 CCR §354.28</u>)

[Sections 6.3.1.2 Minimum Thresholds for Groundwater Levels (p. 6-5)]

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP states that environmental use was considered when establishing the groundwater level minimum threshold; however, the criteria used was not included in the narrative. In addition, Table 6-1 (p. 6-9) does not identify which DMS ID corresponds to GDEs and, or ISWs. Please update this section to provide detail on criteria used to evaluate minimum thresholds for GDEs and ISWs, and to establish proposed thresholds, or a process for establishing thresholds in regards of protecting GDEs and ISWs.

[Section 6.3.3.2 Minimum Thresholds for Water Quality (p. 6-16)]

- *[Our comment was not addressed. No changes to GSP text made.]* Although agricultural water quality concerns were articulated, similar concerns were not identified for GDEs. Please include a discussion about GDEs and water quality, and how the minimum thresholds and interim milestones will help achieve the sustainability goal as it pertains to the environment.

[Sections 6.3.6.2 Minimum Thresholds for Interconnected Groundwater Surface Water Systems (p. 6-35)]

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP states that depletions will be analyzed to determine the location, timing, and quantity of depletions from monitoring data collected between 2020 to 2025 and proposes a qualitative statement of no increased depletions. Please modify this section of the GSP to provide a statement that quantifies gains and, or losses similar to those shown in Table 5-9 (p. 5-172) as they relate to the 2015 conditions.

Checklist Item 30-46 – Undesirable Results (23 CCR §354.26)

[Section 6.3.1.1 Undesirable Results (for chronic lowering of groundwater levels) (p. 6-3)]

- *[Our comment was not addressed. No changes to GSP text made.]* This section only describes undesirable results relating to human beneficial uses of groundwater and neglects environmental beneficial uses that could be adversely affected by chronic groundwater level decline. Please add "potential adverse impacts to GDEs and ISWs" to the list of potential undesirable results presented in Section 6.3.1.1.

[Section 6.3.1.1.2 Identification of Undesirable Results (for chronic lowering of groundwater levels) (p. 6-4)]

- *[Our comment was not addressed. No changes to GSP text made.]* This section states that "..conditions are deemed significant and unreasonable, when groundwater elevations drop below the site-specific minimum threshold of 25% of representative monitoring wells in a principal aquifer…..in a given year". Please describe how a drop below the site-specific minimum threshold of 25% of representative monitoring wells in a principal aquifer relates to undesirable results. A specific threshold should be provided for monitoring wells that measure groundwater levels near GDEs.
- *[Our comment was not addressed. No changes to GSP text made.]* The GDE Pulse web application developed by TNC provides easy access to 35 years of satellite remote sensing data to view trends of vegetation metrics, groundwater depth (where available), and precipitation data. This satellite imagery can be used to observe trends for NC dataset polygons within and near the GSA. Over the past 10 years (2009-2018), some NC dataset vegetation polygons have experienced adverse impacts to vegetation growth and moisture along the San Joaquin River. An example screen shot from the GDE Pulse tool is presented under Checklist Items 11-15 above.
    - For each identifiable GDE unit with supporting hydrological datasets please include the following:
        - Plot and provide hydrological datasets for each GDE.
        - Define the baseline period in the hydrologic data.
        - Classify GDE units as having high, moderate, or low susceptibility to changes in groundwater.
        - Explore cause-and-effect relationships between groundwater changes and GDEs.
    - For each identifiable GDE unit without supporting hydrological datasets please describe data gaps and/or insufficiencies.
    - Compile and synthesize biological data for each GDE unit by including:

        - Plots of biological datasets for each GDE unit, and when possible provide baseline conditions for assessment of trends and variability.
        - Describe data gaps/insufficiencies.
    - Description of potential effects on GDEs, land uses, and property interests, including:
        - Cause-and-effect relationships between GDE and groundwater conditions.
        - Impacts to GDEs that are considered to be "significant and unreasonable".
        - Report known hydrological thresholds or triggers (e.g., instream flow criteria, groundwater depths, water quality parameters) for significant impacts to relevant species or ecological communities.
        - Land uses include and consider recreational uses (e.g., fishing/hunting, hiking, boating).
        - Property interests include and consider privately and publicly protected conservation lands and opens spaces, including wildlife refuges, parks, and natural preserves.

[Section 6.3.3.1.2 Identification of Undesirable Results (for degraded water quality) (p. 6-15)]

- *[Our comment was not addressed. No changes to GSP text made.]* This Section discusses MCLs and WQOs but does not include metrics for GDEs. Please modify this section to specifically address degraded water quality from TDS, As, B and other constituents that could pose a threat to wildlife and / or vegetative communities associated with GDEs and ISWs. Although As and CrVI are mentioned in this section, please add a statement addressing that overpumping and dewatering of aquitards has been identified as a potential source of elevated As concentrations above drinking water standards in San Joaquin Valley aquifers. The following is a link to a paper by Smith, Knight and Fendorf (2018) titled "Overpumping leads to California groundwater arsenic threat": (https://www.nature.com/articles/s41467-018-04475-3.

[Sections 6.3.6 Depletions of Interconnected Surface Water (p. 6-34)]

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP states that depletions will be considered from monitoring data collected between 2020 to 2025. At a minimum the GSP should maintain the current level of ISWs until additional information is collected and measurable objectives and minimum thresholds can be more precisely defined. For example, Table 5-9 (p. 5-172) estimates the quantity of gains and depletions for reaches of the San Joaquin River only. This type of information should be used to support the statement of undesirable results and should be expanded to other streams that are potential ISWs. Please modify this section of the GSP to include a statement that there will be no increase in depletions for confirmed and potential ISWs, at least until data gaps are filled.

Checklist Items 47, 48 and 49 – Monitoring Network (23 CCR §354.34)

[Section 7.2.5.1 Groundwater Level Monitoring Network (p. 7-35)]

- *[Our comment was not addressed. No changes to GSP text made.]* The GSP proposes to use groundwater level monitoring for tracking chronic lowering of groundwater level and as a proxy for groundwater storage and depletion of interconnected surface waters. A set of representative wells has been selected in six subregions, shown in Figure 7-2 (p. 7-33). The representative wells to be used for monitoring groundwater levels in the semi-confined Upper Aquifer and the confined Lower Aquifer are shown in Figure 7-3 (p. 7-39) and Figure 7-4 (p. 7-40). Areas with spatial data gaps have been identified and are shown on both maps. The potential locations for wells for monitoring both aquifers are shown in Figures 7-5 and 7-6 (p. 7-47 and 7-48). Tables 7-6 and 7-7 (p. 7-37 and 7-38) indicate that some wells are missing key information, e.g. status, well depth or screened interval. Although a list of criteria including "adequate construction information" were listed on page 7-41, it appears that not all criteria were met in all the wells. A plan to fill these data gaps is included in Section 7.2.5.6.6 (Plan to Fill Data Gaps) that includes obtaining video logs of some wells and drilling new wells. Please emphasize in the text the importance of using dedicated monitoring wells with complete construction information in order to accurately monitor single aquifers.
- *[Our comment was not addressed. No changes to GSP text made.]* The GSP states on p. 7-45: "Not all wells included in these networks are dedicated monitoring wells, as recommended by DWR's Monitoring Networks and Identifications of Data Gaps BMP (2016a)." The GSP noted that an effort would be made to replace pumping wells with dedicated monitoring wells. Please discuss the importance of using dedicated monitoring wells instead of pumping wells at all locations.
- *[Our comment was not addressed. No changes to GSP text made.]* The GSP states on p. 7-45: "For the purpose of monitoring depletions of interconnected surface water, where groundwater levels are used as a proxy, four additional wells with tentative locations have been identified that would also be included in the groundwater level monitoring network. These wells are located within three miles of the San Joaquin River within the Northwestern Delta-Mendota GSA and Patterson Irrigation District GSA." Consideration should be given to using wells closer to the river or installing new wells. Please discuss how the data will be used to verify ISWs and quantify depletions of stream flow due to groundwater extraction.

[Section 7.2.5.6 Depletions of Interconnected Surface Water Monitoring Network (p. 7-67)]

- *[Our comment was not addressed. No changes to GSP text made.]* At present there are only two wells located within 3 miles of the San Joaquin River in the ISW area. Locations of four clustered wells have been identified and other stream gauging sites proposed as shown in Figure 7-11 (p. 7-73). Please expand on the discussion of how the new well and stream data will be used to improve ISW mapping and inform an adequate analysis. Please discuss how the data will be used to verify possible GDEs and reaches that include ISWs.

- *[Our comment was not addressed. No changes to GSP text made.]* As stated above in the comments for Checklist Items 8-10, please reconcile data gaps (shallow monitoring wells, stream gauges, and nested/clustered wells) along westside ephemeral streams in this section of the GSP to improve ISW mapping in future GSPs.

<u>Checklist Items 50 and 51 – Projects and Management Actions to Achieve Sustainability Goal (23 CCR §354.44)</u>

[Section 7.1 Projects and Management Actions (p. 7-1)]

- *[Our comment was not addressed. No changes to GSP text made.]* The Subbasin includes many potential GDEs and ISWs (see our comments under Checklist Items 8-10 and 16-20 above) that are beneficial uses and users of groundwater and may include sensitive resources and protected lands. Environmental resource protection needs should be considered in establishing project priorities. In addition, and consistent with existing grant and funding guidelines for SGMA-related work, priority should be given to multi-benefit projects that can address water quantity and quality as well as providing environmental benefits or benefits to disadvantaged communities.
    - Although Table 7-2 (p. 7-5) provides information on how each project supports ISWs there are no criteria provided on how GDEs and ISWs were considered in project selection. Please include criteria considered for project selection as it relates to GDEs and ISWs.
    - In Section 7.1.1.1.1 (p. 7-9), the narrative supporting the Los Banos Creek Recharge and Recovery Project states that project beneficiaries are groundwater users but there is no discussion about how environmental users (i.e., GDEs and ISWs) will specifically benefit. Please update the environmental benefits and multiple benefits as criteria for assessing project priorities and articulate how project monitoring will support GDEs and ISWs.
    - Table 7-2 (pp. 7-5 to 7-8) identifies many important projects; however, the descriptions of objectives for each sustainability indicator for these projects only identify benefits to water level and storage. Since maintenance or recovery of groundwater levels, or construction of recharge facilities, may have potential environmental benefits in many cases it would be advantageous to demonstrate these multiple benefits from a funding and prioritization perspective. For the projects already identified, please consider stating how ISWs and GDEs will benefit or be protected, or what other environmental benefits will accrue.
    - If ISWs will not be adequately protected or enhanced by those listed, please include and describe additional management actions and projects targeted for protecting known and potential ISWs.

- Recharge ponds, reservoirs and facilities for managed stormwater recharge can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. In some cases, such facilities have been incorporated into local Habitat Conservation Plans (HCPs) and Natural Community Conservation Plans (NCCPs), more fully recognizing the value of the habitat that they provide and the species they support. In addition, incorporating HCPs, NCCPs, and managed wetlands into recharge projects may effectively tie into the project's permitting strategy described in Section 7.1.5. For projects that construct recharge ponds, please update Table 7-4 (p. 7-21) to identify if there are multi-benefit opportunities that can incorporate habitat components into project designs and how the recharge ponds will be managed to benefit environmental uses and users.
- For examples of case studies on how to incorporate environmental benefits into groundwater projects, please visit our website: https://groundwaterresourcehub.org/case-studies/recharge-case-studies/

[Section 7.1.1.2 Tier 1 Management Actions (p. 7-12)]

- *[Our comment was not addressed. No changes to GSP text made.]* This section discusses the Management Actions for GSP implementation and SGMA compliance; however, these actions are focused on meeting groundwater level and storage measures and do not include support for GDEs or ISWs. Please modify the Management Actions to include education and outreach for GDEs, ISWs and the sensitive habitats they support. Please update Section 7.1.1.2 Tier 1 Management Actions (p. 7-12) and Section 7.1.1.4 Tier 2 Management Actions (p. 7-15) to include GDEs and ISWs.

Attachment C

Freshwater Species Located in the San Joaquin Valley Delta Mendota Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Oxnard Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the GSA's boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[3]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the CDFW's BIOS[4] as well as on TNC's science website[5].

IDENTIFYING GDEs UNDER SGMA

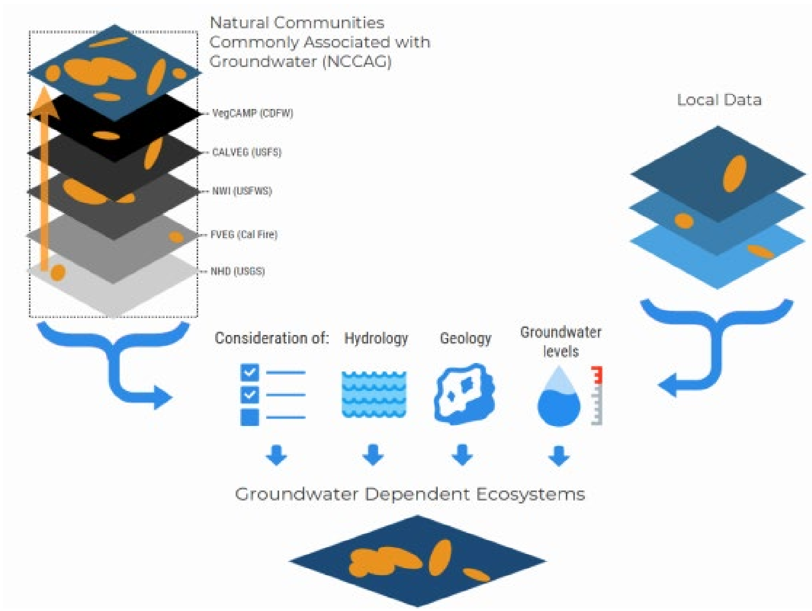
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[6] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[7]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.

---

[6] *NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/*

[7] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf



The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[8]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[9] on the Groundwater Resource Hub[10], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may

---

[8] *For more details on the mapping methods, refer to: Klausmeyer, K., J. Howard, T. Keeler-Wolf, K. Davis-Fadtke, R. Hull, A. Lyons. 2018. Mapping Indicators of Groundwater Dependent Ecosystems in California: Methods Report. San Francisco, California. Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/iGDE_data_paper_20180423.pdf*
[9] "Groundwater Dependent Ecosystems under the Sustainable Groundwater Management Act: Guidance for Preparing Groundwater Sustainability Plans" is available at: https://groundwaterresourcehub.org/gde-tools/gsp-guidance-document/
[10] *The Groundwater Resource Hub: www.GroundwaterResourceHub.org*

become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

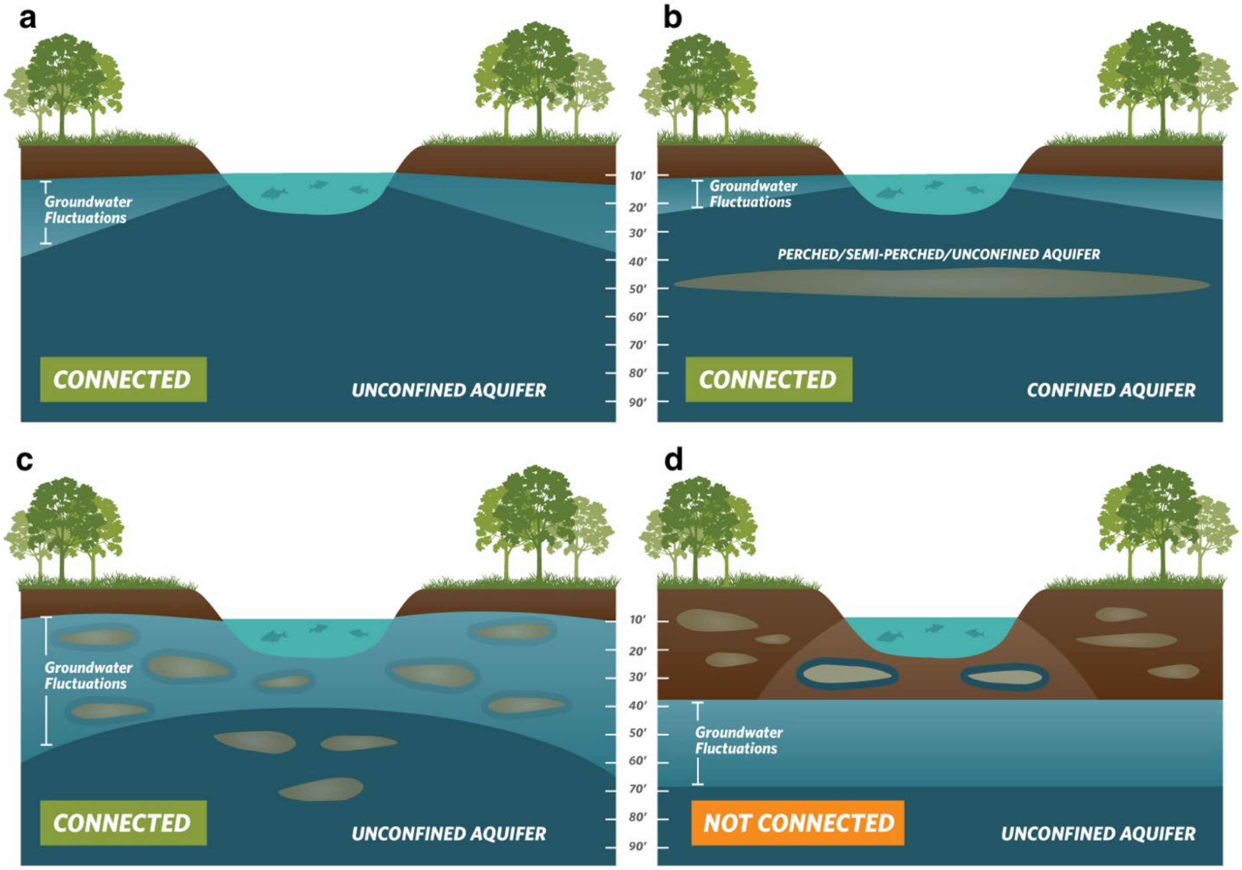


Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[11] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[12] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[13] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[14]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP <u>until</u> data gaps are reconciled in the monitoring network (see Best Practice #6).

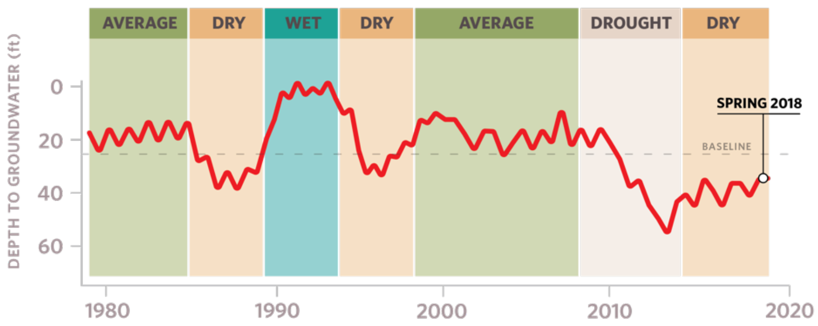

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

---

[11] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[12] *Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]*

[13] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[14] *SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer*

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[15], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

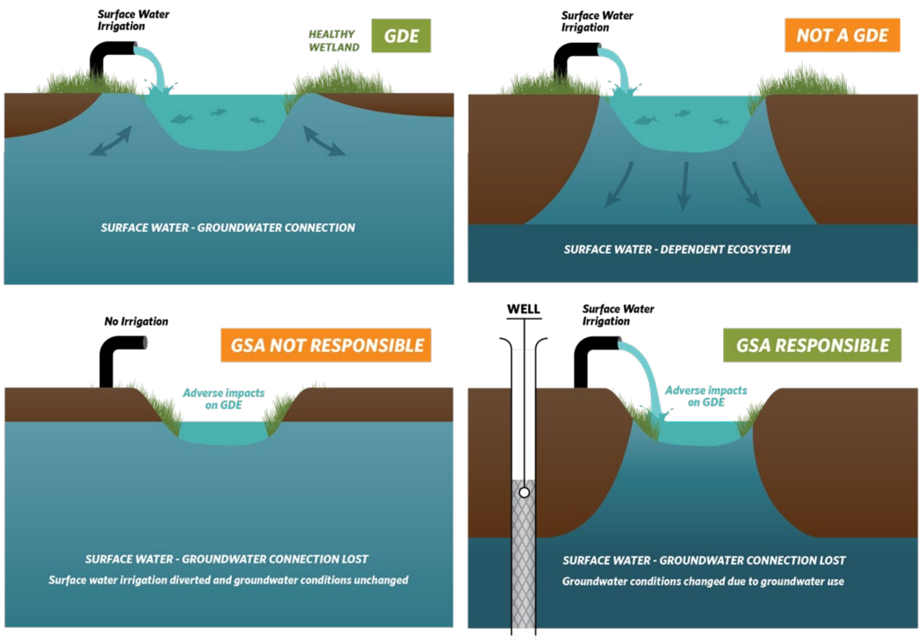

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[15] *For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/*

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

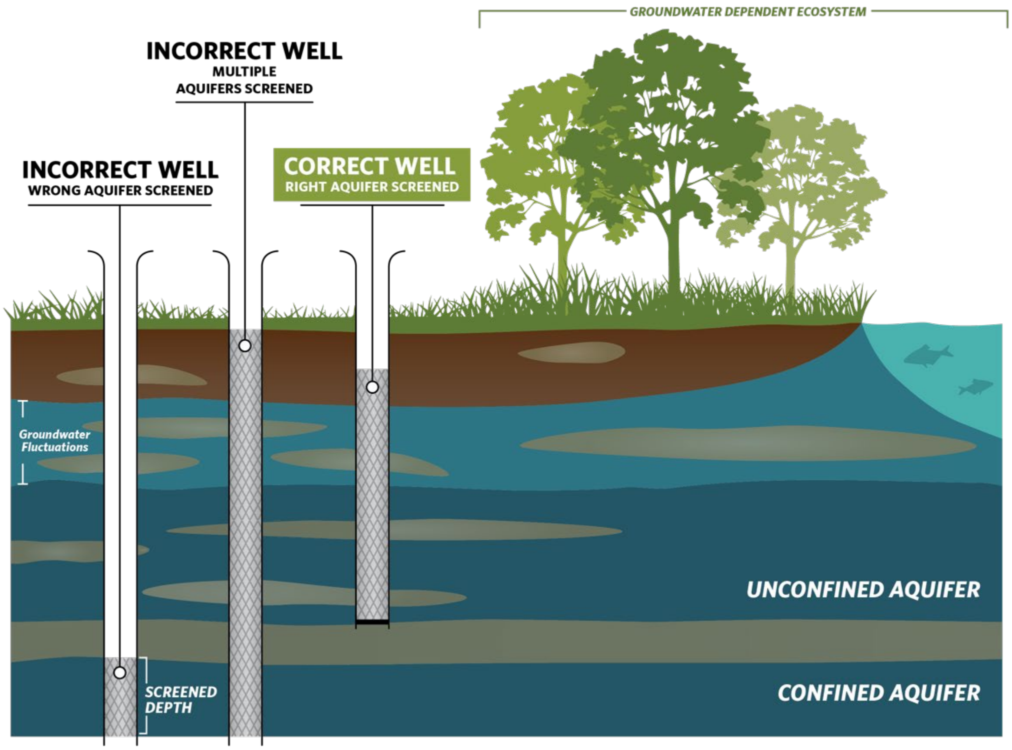

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[16] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

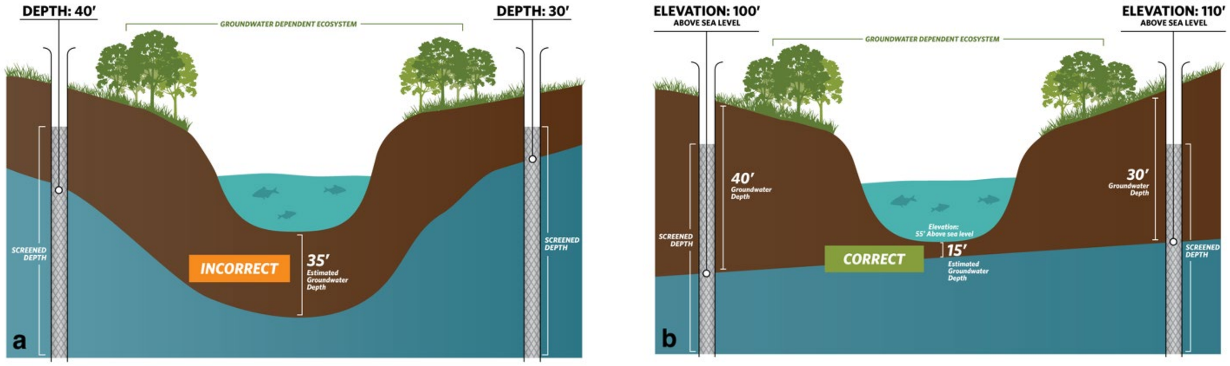

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

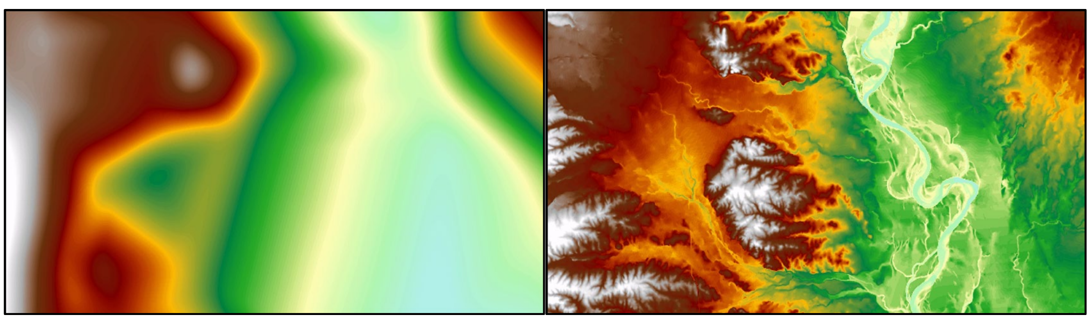

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Protecting nature. Preserving life.®

Visit
https://gde.codefornature.org/

Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset[17]. The following datasets are included:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset[18]. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

Mapping Likely Interconnected Surface Water
The Nature Conservancy, California, May 2020

Sustainable groundwater management in California requires an understanding of how groundwater pumping affects surface water features. Groundwater seeps into many river and lake beds in California, providing a steady source of cool clean water. This source of water is crucial for people and nature because it remains steady throughout the year even after the winter rains stop. Under SGMA, ISW is defined as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted" (Groundwater Sustainability Plan Emergency Regulations). SGMA requires special treatment of ISW, but in many parts of the state, ISW is poorly understood. This set of maps displays rivers and streams that are likely ISW, using groundwater depth as a proxy to determine ISW.

Methods and Data Sources:
The groundwater elevation data, available for Spring 2011-2012, and Spring and Fall 2013-2018, comes from the California Department of Water Resources (https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer). These data are represented as continuous raster layers that approximates "feet above or below mean sea level" based on groundwater well measurements. According to the documentation online, groundwater level measurements were selected based on measurement date and well construction information (where available) and are intended to approximate the groundwater levels in the unconfined to uppermost semi-confined aquifers. Each of the raster layer has a different extent, but all of them are limited to the Central Valley. To determine ISW, we used ArcGIS software to calculate the average, minimum, and maximum groundwater elevation. Next, we subtracted the elevation grids from the statewide 30-meter resolution digital elevation model (DEM). The resulting layers represent the mean, minimum, and maximum *depth* to groundwater, expressed in feet below the ground surface. Finally, we used flowline data from the National Hydrography Dataset Plus (https://nhdplus.com/NHDPlus/NHDPlusV2_home.php) to assign groundwater depth values to rivers and streams. We developed a new shapefile of stream segments with three new attributes: mean, minimum, and maximum groundwater depth.

The map splits groundwater depth into four categories:

- Connected – Gaining. Groundwater depth is at or above stream surface levels and thus is likely flowing into the surface water body.
- Connected – Losing. Groundwater depth is between 0 and 20 ft. of the stream surface level and thus is likely receiving water from the water body through a continuous saturated zone.
- Uncertain. Groundwater depth between 20 and 50 ft. below the stream surface is labeled as uncertain and may or may not be connected to surface water.
- Likely Disconnected. Groundwater depth greater than 50 ft. below the stream surface is likely disconnected from surface water.

There is no comprehensive data on stream depth, we analyzed all the gage height measurements from USGS gages in the Central Valley. For some (17%) of the stream gages, the average gage height measurement was greater than 20 feet. This is only a proxy for stream

height because gage height is measured from a reference elevation which may or may not be the bottom of the stream bed. Based on this information, we chose a break point of 20ft between losing and uncertain streams.

TNC as a Representative for Environmental Beneficial Users

The state of California contains more species of plants and animals than the rest of the United States and Canada combined[19]. For over 200 years, California's natural ecosystems have been converted to agricultural and urban landscapes. This modification of land and water has resulted in approximately 95% reduction in the historical extent of California's aquatic and wetland habitats[20]. Subsequently, more than 90% of all native freshwater species endemic to California are vulnerable to extinction[21] within the next 100 years. To prevent this, water managers at every scale have a responsibility to manage groundwater sustainably, meeting the needs of people and the environment. TNC is working to help by providing the science, tools and solutions needed to halt the decline of our freshwater biodiversity.

Important Plan Evaluation Provisions

Per the Emergency Regulations Section 355.4(b), the Department shall evaluate plans for compliance considering ten factors, including the following, which are of particular interest to TNC:

(1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science.

(2) Whether the Plan identifies reasonable measures and schedules to eliminate data gaps.

(4) Whether the interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have been considered.

(10) Whether the Agency has adequately responded to comments that raise credible technical or policy issues with the Plan.

Re: Paso Robles Subbasin Groundwater Sustainability Plan (GSP)

Dear DWR Representative,

The Nature Conservancy (TNC) appreciates the opportunity to comment on the Paso Robles Subbasin Groundwater Sustainability Agency's (GSA's) Groundwater Sustainability Plan (GSP or Plan) prepared under the Sustainable Groundwater Management Act (SGMA).

Addressing Nature's Water Needs in GSPs

SGMA requires that all beneficial uses and users, including environmental users of groundwater be considered in the development and implementation of GSPs (Water Code § 10723.2, 23 CCR §355.4(b)(4)). The inclusion of natural communities in the management our state's groundwater resources is essential to protect and restore habitat and wildlife, and as such, is an important factor in distinguishing *sustainable* groundwater management from the status quo.

TNC Summary of GSP Review

TNC has carefully reviewed the Plan and we appreciate the work that has gone into its preparation. Based on our review, we found the Plan to be insufficient in addressing environmental beneficial uses and users.

The identification of environmental beneficial users, as well as their consideration when establishing the sustainability goal, undesirable results and minimum thresholds were insufficient (23 CCR §355.4(b)(4)) and lacked best available science (23 CCR §355.4(b)(1)). In the face of existing, severe overdraft, the GSP would allow groundwater management to largely ignore potential impacts to environmental beneficial users. This could result in irreparable harm to these beneficial users, undermining the intent of SGMA to achieve sustainability.

Many of the gaps can be addressed now, and we encourage the Department to require these corrections prior to approval. In some cases, it may be difficult to address within 180 days. In these cases, we strongly recommend that the Department, at a minimum, set clear expectations that these be corrected in the 2025 plan update and, to the degree that gaps are due to lack of data, that these data gaps be addressed in time to inform the 2025 update. Should the treatment of environmental beneficial users be indicative of the quality of the overall plan, then we recommend the Department deem the plan inadequate.

To assist in managing groundwater for the needs of natural communities, we provide a summary of our technical review below. Our specific comments are detailed in Attachment B and are in reference to numbered items in the checklist in Attachment A. Attachment C provides a list of the freshwater species located in the Subbasin. Attachment D describes six best practices to confirm a connection to groundwater for DWR's NC Dataset. Attachment E provides an overview of a tool (i.e., GDE Pulse) that assesses changes in GDE health using satellite, rainfall, and groundwater data.

Our Key Considerations

Engagement of Environmental Beneficial Users – Stakeholder engagement can best be measured by the degree to which stakeholders are able to influence the plan. TNC provided feedback to the draft GSP, which can be found as a comment attached to the SGMA portal website's GSP Initial Notifications section. We are disappointed to see the feedback that we provided on the draft GSP has been ignored in the final plan, as none of 41 comments were adequately addressed in the Final GSP. This indicates poor engagement of environmental beneficial users, which undermines the intent of SGMA to ensure that sustainability be defined locally with the participation of all users. Based on our experience the GSP did not "adequately respond to comments that raise credible technical or policy issues with the Plan" (23 CCR §355.4(b)(10)).

TNC recommendation: We strongly recommend that DWR require the GSA to prioritize stakeholder engagement through improvements to their stakeholder engagement plan, partnerships, more representative governance and funding decisions. Because the GSP does not adequately incorporate feedback from environmental beneficial users, we also recommend the GSP revisit all components of the plan where beneficial users must be considered, especially in calculating the water budget and determining undesirable results, minimum thresholds and measurable objectives.

Interconnected Surface Waters (ISWs) – The GSP incorrectly excluded potential and/or actual ISWs because the plan did not employ the best available science. The GSP therefore lacks an assessment of whether surface water depletions caused by groundwater use are having an adverse impact on environmental beneficial users of surface water (23 CCR §354.28(c)(6)). The assessment of potential ISWs is based on an incomplete groundwater level dataset that lacks sufficient characterization of shallow groundwater levels near streams, and appears to be based in part on the mistaken assumption that ephemeral streams cannot be ISWs. The regulations [23 CCR §351(o)] define interconnected surface waters (ISW) as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. Identification of ISWs is recognized as a data gap in the GSP, but the GSP does not outline any specific actions to address this important data gap.

TNC recommendation: TNC recommends that consideration be given to existing data gaps by installing shallow monitoring wells, stream gauges, and nested/clustered wells along surface water features to improve ISW mapping, characterization and management. Furthermore, until a disconnection can be proven, TNC recommends that the GSP include all potential and confirmed ISWs. Where data gaps exist, we recommend that the GSP describe concrete actions, with a timeline and budget, to increase the number of monitoring wells in proximity to streams to fill data gaps and properly identify the dynamics between groundwater and surface water. Please see our detailed feedback in Attachment B.

Groundwater Dependent Ecosystem (GDEs) – According to the Natural Communities Commonly Associated with Groundwater dataset (NC Dataset), 375 acres of potential GDEs occur in the GSA boundary. TNC developed the Groundwater Dependent Ecosystems under SGMA: Guidance for Preparing GSPs[1], which represents the best available science on how GDEs should be considered in plans. The guidance includes methods for how GSAs should confirm or eliminate GDEs, starting with the NC Dataset.

The plan does not to adequately identify, map and consider GDEs. We believe that this falls short of meeting plan evaluation criteria (1), (4) and (10), as defined in the 23 CCR §355.4(b). In addition, the Plan does not satisfy the requirement to identify GDEs (23 CCR §Section 354.16(g)) and consider beneficial users throughout the plan. Our review found that NC Dataset polygons were improperly removed from the GDE map based on the following:

- The analysis described in Appendix C of the GSP relies on groundwater levels at a single point in time (Spring 2017), which is *after* the January 1, 2015 SGMA benchmark date, and makes no further attempt to resolve questions of whether or not potential GDEs are groundwater connected or the degree to which they may be adversely affected by groundwater level declines. Furthermore, the GSP does not consider GDEs when defining undesirable results, minimum thresholds or measurable objectives. Finally, the groundwater monitoring data provided are insufficient to characterize the interaction between shallow groundwater and GDEs, the GSP does not establish monitoring networks capable of identifying potential undesirable results related to GDEs, and no specific plans are provided to address these data gaps.

<u>TNC recommendation</u>: The GSP utilizes groundwater levels that represent interannual and inter-seasonal variability along with additional information provided in Attachment D, which provides best practices for using the NC Dataset to identify and consider GDEs in the GSP. Specifically, please ensure that a Digital Elevation Model (DEM) is used when developing depth to groundwater contours, as further described in Best Practice #5 in Attachment D.

Water Budget – We were disappointed to see that the water budget did not include the current, historical and projected demands of native vegetation and/or managed wetlands, as required under SGMA (23 CCR §354.18(a) and (b)(3)). The GSP only focused on a subset of water use sectors, such as urban and agricultural users of groundwater. This is problematic because key environmental uses of groundwater are not being accounted for as water supply decisions are made using this budget nor will they likely be considered in project and management actions.

<u>TNC recommendation:</u> As required by SGMA, TNC recommends explicit inclusion of all water use sectors in the water budget.

Sustainable Management Criteria – We were disappointed to see that the Sustainable Management Criteria do not describe potential impacts on environmental users of groundwater and or confirm that minimum thresholds for interconnected surface waters avoid adverse impacts to environmental beneficial users of surface water, as required under SGMA (23 CCR §354.26(b)(3), 354.28(b)(4) and (c)(B)(6)). This is problematic because without identifying

[1] Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf

potential impacts to GDEs and adverse impacts to beneficial users of surface waters, minimum thresholds may be set incorrectly.

TNC recommendation: As required by SGMA, the undesirable results should include a description of potential effects on environmental beneficial uses and users of groundwater (i.e., GDEs and instream habitats within ISWs). In addition, the GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of surface waters. Both of these recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.

Monitoring Network – We were disappointed to see that the monitoring network is not designed to, as required by 23 CCR §354.34: (1) ensure adequate coverage of the sustainability indicators, (2) characterize the spatial and temporal exchanges between surface water and groundwater, nor (3) calibrate and apply the tools and methods necessary to calculate the depletions of surface water caused by groundwater extractions. The Monitoring Network, which emphasizes groundwater level monitoring in deeper production aquifers and largely omits the alluvial aquifer and areas near potential GDEs and ISWs, is not sufficient to establish a linkage between groundwater extraction and resulting potential impacts to GDEs and ISWs. As a result, the monitoring network does not adequately characterize GDEs and other environmental beneficial users of surface water and groundwater.

TNC recommendation: TNC recommends that the GSP (1) reconcile data gaps in the monitoring network by evaluating how the gathered data will be used to identify and map GDEs and ISWs; (2) characterize groundwater conditions within GDEs and ISWs (e.g., discuss how monitoring data will be used to estimate the quantity and timing of streamflow depletions); and (3) determine what ecological monitoring can be used to assess potential impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

In closing, SGMA is based on two important ideas. First, California's goal is not just groundwater management, but *sustainable* groundwater management that considers the needs of all beneficial users. This goal can only be achieved when input from environmental beneficial users is reflected in the plan. Second, SGMA is a long-term commitment to continually improve sustainable groundwater management. The Department has a critical role in maintaining a high bar for plan approval and setting the expectation that each plan, and the resulting groundwater conditions, improve over time.

Best Regards,

Sandi Matsumoto
Associate Director, California Water Program
The Nature Conservancy

TNC Evaluation of the
Paso Robles Subbasin Groundwater Sustainability Plan

The Paso Robles Subbasin Groundwater Sustainability Plan (GSP), dated January 31, 2020, was reviewed by TNC. Public comments received on the draft GSP were included as Appendix N to the GSP. The comments are stated to have been reviewed by the Paso Roble Subbasin Groundwater Sustainability Agencies (PRSGSA) and changes incorporated into the GSP text as deemed appropriate by them; however, no response to comments were provided. We reviewed the text of the Final GSP to determine if changes were made to the Final GSP text that addressed TNC's previously submitted comments. This attachment lists our original comments on the complete Public Draft GSP, as submitted to the PRSGSA during the public comment period, and states whether or not they were addressed in the Final GSP *[as green text within brackets]*. Comments are provided in the order of the checklist items included as Attachment A.

<u>Checklist Item 1 - Notice & Communication (23 CCR §354.10)</u>

[Chapter 11 Notice and Communications (including separate Communications and Engagement Plan, Appendix M)]

- *[The PRSGSA did not address this comment. No GSP text changes were made.]* Section 3.0 of the Communications and Engagement Plan (Page 6) lists aquatic ecosystems as a beneficial groundwater use. **However, no details are given as to the types and locations of environmental uses and habitats supported, or the designated beneficial environmental uses of surface waters that may be affected by groundwater extraction in the subbasin. To identify environmental users, please refer to the following**:
    - Natural Communities Commonly Associated with Groundwater dataset (NC Dataset) - https://gis.water.ca.gov/app/NCDatasetViewer/
    - The list of freshwater species located in the Paso Robles Subbasin in **Attachment C** of this letter. Please take particular note of the species with protected status.
    - Lands that are protected as open space preserves, habitat reserves, wildlife refuges, etc. or other lands protected in perpetuity and supported by groundwater or ISWs should be identified and acknowledged.

<u>Checklist Items 2 to 4 - Description of general plans and other land use plans relevant to GDEs and their relationship to the GSP (23 CCR §354.8</u>

[Section 3.6 Existing Monitoring Programs (p. 3-17)]

- *[The PRSGSA did not address this comment. No GSP text changes were made.]* Per the GSP Regulations (23 CCR §354.34 (a) and (b)), monitoring must address trends in groundwater and *<u>related surface conditions</u>* (emphasis added). In order for this section to provide the appropriate context and help assure integration of GSP implementation with other ongoing regulatory programs, this section should describe the following:

- **Monitoring activities and responsibilities by State, Federal and local agencies and jurisdictions related to aquatic resources and GDEs that could be affected by groundwater withdrawals should be discussed.**
- The Critical Habitat for Threatened and Endangered Species website maintained by the US Fish and Wildlife Service (https://fws.maps.arcgis.com/home/webmap/viewer.html?webmap=9d8de5e265ad4fe09893cf75b8dbfb77) identifies lands with endangered and threatened species in the Basin, including species potentially associated with interconnected surface waters ISWs, including Steelhead (Onocorhynchus mykiss). Also please refer to the Critical Species Lookbook[2] to review and discuss the potential groundwater reliance of critical species in the basin. **Please include a discussion regarding the management of critical habitat for these aquatic species and its relationship to the GSP.**

[Section 3.8.6 Requirements for New Wells (p. 3-30)]

- *[The PRSGSA did not address this comment. No GSP text changes were made.]* **Future well permitting must be coordinated with the GSP to assure achievement of the Plan's sustainability goals.**
- *[The PRSGSA did not address this comment. No GSP text changes were made.]* The State Third Appellate District recently found that Counties have a responsibility to consider the potential impacts of groundwater withdrawals on public trust resources when permitting new wells near streams with public trust uses (ELF v. SWRCB and Siskiyou County, No. C083239). **The need for well permitting programs to comply with this requirement should be stated.**

[Section 3.10 Land Use Plans (p. 3-31)]

- *[The PRSGSA did not address this comment. No GSP text changes were made.]* This section should include a discussion of General Plan goals and policies related to the protection and management of GDEs and aquatic resources that could be affected by groundwater withdrawals. **Please include a discussion of how implementation of the GSP may affect and be coordinated with General Plan policies and procedures regarding the protection of wetlands, riparian areas, oak woodlands, aquatic resources and other GDEs and ISWs.**
- *[The PRSGSA did not address this comment. No GSP text changes were made.]* This section should identify Habitat Conservation Plans (HCPs) or Natural Community Conservation Plans (NCCPs) within the Subbasin and if they are associated with critical, GDE or ISW habitats. **Please identify all relevant HCPs and NCCPs within the Subbasin and address how GSP implementation will coordinate with the goals of these HCPs or NCCPs.**

Checklist Items 5, 6, and 7 – Hydrogeologic Conceptual Model (23 CCR §354.14)

[Section 4.1 Subbasin Topography and Boundaries (p. 4-1)]

- *[The PRSGSA did not address this comment. No GSP text changes were made.]* Please provide additional information on what data was used to determine that "poor quality" groundwater in the Paso Robles Formation would exclude groundwater from being part of the subbasin.
- *[The PRSGSA did not address this comment. No GSP text changes were made.]* Defining the bottom of subbasin based on geochemical properties is a suitable approach for defining the base of freshwater, however, as noted on page 9 of DWR's Hydrogeologic Conceptual Model BMP (https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_HCM_Final_2016-12-23.pdf) "the definable bottom of the basin should be at least as deep as the deepest groundwater extractions". **Thus, groundwater extraction well depth data should also be included in the determination of the basin bottom.** This will prevent the possibility of extractors with wells deeper than the basin boundary (defined by the base of freshwater) from claiming exemption of SGMA due to their well residing outside the vertical extent of the basin boundary.

[Section 4.7.2 Groundwater Discharge Areas Inside the Subbasin (p. 4-32)]

- We support the use of the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) to map groundwater dependent ecosystems in the Paso Robles Groundwater Basin (GSP Draft Figure 4-18). Since the NC Dataset is intended as a starting point, The Nature Conservancy has developed a Guidance Document to assist GSAs and their consultants in addressing GDEs in GSPs[3]. Also refer to **Attachment D** for best practices when using the NC dataset.
- *[The PRSGSA did not address this comment. No GSP text changes were made.]* The identification of GDEs within GSPs is a required GSP element of the Basin Setting Section under the description of Current & Historical Groundwater Conditions (23 CCR §354.16). Recognizing natural points of discharge (seeps & springs) as GDEs is consistent with the SGMA definition of GDEs;[4] **however, we recommend the identification of GDEs (GDE map Figure 4-18) for the Paso Robles basin be moved to Chapter 5: Groundwater Conditions, and elaborated upon with a description of current and historical groundwater conditions in the GDE areas.** Chapter 5 is a more appropriate place for the identification of GDEs, since groundwater conditions (e.g., depth to groundwater, interconnected surface water maps, groundwater quality) are necessary local information and data from the GSP in assessing whether polygons in the NC dataset are connected to groundwater in a principal aquifer.
- *[The PRSGSA did not address this comment. No GSP text changes were made.]* Decisions to remove, keep, or add polygons from the NC dataset into a basin GDE

[3] GDEs under SGMA: Guidance for Preparing GSPs is available at: https://groundwaterresourcehub.org/public/uploads/pdfs/GWR_Hub_GDE_Guidance_Doc_2-1-18.pdf
[4] Groundwater dependent ecosystem refer to ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. [23 CCR §351 (m)]
